RE: Letter of Transmittal
Baseline Risk Assessment
American Chemical Services NPL Site
Project # 60251

Dear Mr. Hartwick:

Enclosed is a copy of the Baseline Risk Assessment for the ACS NPL Site. It has been revised in accordance with the U.S. EPA comments dated August 19, 1991 and August 28, 1991.

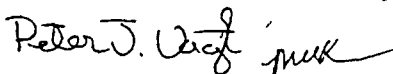

The document does not contain section 7.2, the Ecological Assessment. We have not been able to respond to all the Biological Team Assessment Group (BTAG) comments, partly because the AQUIRE database is not yet available from NTIS.

I discussed this difficulty with you in a telephone conversation on September 18, 1991. You agreed that we should submit just the completed section, the Baseline Risk Assessment, and submit the Ecological Assessment after we have been able to obtain the necessary information.

We discussed setting up a conference call between BTAG and Warzyn as soon as possible to resolve the data issues. One of the quickest solutions would be if BTAG could provide the necessary information directly to us.

Sincerely yours,

WARZYN INC.

Peter J. Vagt, Ph.D.

SECTION 7.0

BASELINE RISK ASSESSMENT

7.1 HUMAN HEALTH EVALUATION

7.1.1 Introduction

Section 300.430 of the National Oil and Hazardous Substances Pollution Contingency Plan (NCP 1990) states that the purpose of the remedial process for a contaminated site is to implement remedies that reduce, control, or eliminate risks to human health and the environment. The mandate of the Superfund program is to protect human health and the environment from current and potential substance releases, as enforced in the NCP.

Under CERCLA and the Superfund process, a Baseline Risk Assessment is the vehicle or tool which may be used to evaluate the potential threats to public health and the environment from a site in the absence of any remedial action (U.S. EPA, 1988). It identifies and characterizes the toxicological characteristics of the contaminants of concern, the potential exposure pathways, the potential human and environmental receptors, and the potential health impact the site may pose. The information obtained through risk assessment is used to assist in the evaluation of possible remedial measures to reduce risk at a site.

This Baseline Risk Assessment addresses the potential risks associated with the American Chemical Services Site (Site) under the "no-action" alternative. The no-action alternative assumes that no corrective actions will take place and no restrictions will be placed on future use of the Site.

The Baseline Risk Assessment for the Site was performed consistent with the Risk Assessment Guidance for Superfund (RAGS, U.S. EPA, 1989). In addition, guidance recommended in RAGS for conducting specific parts of the risk assessment were used to the extent practicable.

The Baseline Risk Assessment is based on the following major assumptions:

- No corrective actions will take place and no restrictions will be placed on future use of the Site.
- There are no groundwater use restrictions.
- There is the potential for future development of the Site.
- Contaminant concentrations in various media are assumed not to change over time.

7.1.1.1 Organization

The Baseline Risk Assessment is organized into the following sections:

- Identification of Chemicals of Potential Concern
- Toxicity Assessment
- Exposure Assessment
- Risk Characterization

Identification of Chemicals of Potential Concern - This component consists of a review of the data collected during the remedial investigation at the Site in view of data validity, chemical concentrations, media in which the chemicals have been detected, frequency of chemical detection, the toxic properties of the chemicals, the physical properties of each chemical as they relate to fate and migration potential, and the conditions of potential exposure to identified human receptors.

Toxicity Assessment - The toxicity assessment is a determination of the quantitative and qualitative relationship between the magnitude of exposure to chemicals of potential concern at the Site and the probability of occurrence of adverse health effects from that exposure.

Exposure Assessment - This element of the Baseline Risk Assessment identifies populations potentially exposed to Site contamination and evaluates the potential magnitude and duration of their exposure.

Risk Characterization - This final element integrates the toxicological information for the chemicals of potential concern with potential exposure considerations to arrive at an estimate of public health risk.

7.1.1.2 Background

Previous sections of the Site Remedial Investigation (RI) Report provide descriptions of the Site location, history, physical characteristics (i.e., geology, hydrogeology, etc.), and sampling locations and media. Also included in previous sections is a discussion of the Site chemistry as it relates to sample locations and chemical fate and migration.

Information presented in these previous sections has been used in the Baseline Risk Assessment to assist in assessing public health risk. Reference to appropriate sections of the RI Report should be made for detailed discussions of the background information.

Because of the large area within the Site RI/FS boundary, the numerous media affected by contamination, and several discrete areas where contamination sources exist, the Site was divided into nine operable areas (areas) including the Griffith Municipal Landfill, for evaluation in the risk assessment. These areas are defined as follows:

- Groundwater - Upper Aquifer
- Groundwater - Lower Aquifer
- Surface Water
- Sediments
- On-Site Containment Area - Subsurface Contamination
- Still Bottoms and Treatment Lagoon - Subsurface Contamination
- Off-Site Containment Area - Subsurface Contamination
- Kapica-Pazmey Area - Surface and Subsurface Contamination
- Griffith Municipal Landfill

These nine areas have been evaluated with respect to the contamination present at each location. In defining these areas, potential exposure pathways and Feasibility Study needs were taken into consideration. Table 7-1 provides a summary of samples collected and analyzed for at each of the above areas.

7.1.2 Identification of Chemicals of Potential Concern

The identification of chemicals of potential concern at the Site involved a number of steps. These steps, as outlined in the guidance, have been used to arrive at a list of chemicals of potential concern which were subsequently evaluated in the Baseline Risk Assessment.

7.1.2.1 Chemical Analysis of Site Media

After evaluating the quality/validity of data obtained from the performing Contract Laboratory Program (CLP) laboratories, numerous chemicals were determined to be present in various media at the Site. Twenty-seven Target Compound List (TCL) volatiles were detected in various media as were 51 TCL semivolatiles, 14 TCL pesticides/PCBs, more than 400 tentatively identified compounds (TIC), and the full Target Analyte List (TAL) of metals. Tables 7-2 through 7-10 present the chemicals detected in the designated source areas at the Site along with their respective minimum, maximum, and arithmetic average concentrations, and frequency of detection.

The chemical analyses of samples were performed through the CLP and have been evaluated as to their usability in accordance with U.S. EPA guidance for validation of organic and inorganic analyses of environmental samples (U.S. EPA, 1988a and b). Data used in the present risk assessment include unqualified data and data which represent estimated quantities (qualified J). For a description of the evaluation of data quality, refer to Appendix Q of the RI Report.

7.1.2.2 Development of a Set of Chemical Data and Information for Use in the Risk Assessment

The following describes the rationale for selection or exclusion of identified chemicals in the data set as chemicals of potential concern for further evaluation in the risk assessment. The process of identifying chemicals of potential concern and which samples to include in the evaluation, is an integrated procedure.

As suggested in recent guidance, chemicals that exhibit the following characteristics are to be included in a set of chemical data and information for use in the Baseline Risk Assessment:

- Positively detected in at least one CLP sample in a given medium. Positively detected chemicals include both unqualified results and results qualified as estimated but with known identities (J-qualified Target Compound List data);
- Determined to be present at the Site and not due to contamination introduced during sampling or analysis;
- Determined to be the result of chemical releases from the Site and not natural background levels;
- Tentatively identified compounds associated with the Site; and
- Transformation products of chemicals demonstrated to be present.

The above criteria were applied to each of the areas defined earlier and for all chemicals positively detected at the Site (refer to Appendix S for a detailed discussion of the preceding approach and its application to each of the defined areas).

Because more than 400 tentatively identified compounds were detected at the Site, it was necessary to group these chemicals based on similar chemical structure. Forty-four groups were identified and a specific chemical was selected to represent each individual group. Table 7-11 shows the chemical groups and Table 7-12 indicates the representative chemical selected for each group and a brief description of the rationale for the selection. When possible, the representative chemical was selected such that the group's toxicity might be evaluated on the basis of a similar chemical with an existing toxicity value. This approach was agreed upon by the U.S. EPA, Region V Technical Support Group. The decision logic applied to the TICs is illustrated in the decision tree in Figure 7-1.

The result of the above processes culminated in most chemicals detected at the Site being included in the risk assessment as chemicals of potential concern. The final list of chemicals of potential concern based on the above criteria for each area are presented in Table 7-13.

7.1.3 Exposure Assessment

The exposure assessment is performed to identify actual and potential pathways by which human exposure to contaminated Site media might occur. The assessment considers factors such as the physical location of contaminated areas, the type of contamination, and the populations which may come into contact with these areas. Exposure pathways are identified for two Site land-use scenarios: 1) pathways based on land-use practices as they currently exist, and 2) potential pathways based on land-use changes which may occur in the future and result in additional types of exposure.

Both current and future pathways which represent possible exposures were then quantified in order to estimate the magnitude of daily contaminant exposure a population may incur. To accomplish this, assumptions pertaining to the exposed population were made such as, the nature of the individuals (as child vs. adult), the rate of contact with the contaminated medium (e.g., adult consumes 2 liters of water daily), and the length of time the exposure is likely to occur (e.g., years vs. lifetime). These population variables are then integrated with chemical concentration data to calculate a level of exposure (or dose).

7.1.3.1 Exposure Setting

7.1.3.1.1 Location of Site

The Site is located at and near 420 South Colfax Avenue in Griffith, Indiana. The Site is located in the northeast one-quarter of the southeast one-quarter, Section 2, Township 35 North, Range 9 West, Lake County, Indiana (Figure 1-1). Although the Site name is American Chemical Services (ACS), the U.S. EPA has defined the Site as including the ACS property (19 acres), the Pazmey Corporation property (2 acres; formerly Kapica Drum, Inc.), and the inactive portion of the Griffith Municipal Landfill (about 15 acres).

The Site is bordered on the east and southeast by Colfax (Arbogast) Avenue. The Chesapeake and Ohio Railroad right-of-way bisects the Site in a northwest-southeast direction, between the fenced Site compound area and the off-site areas. On the west and southwest, south of the Chesapeake and Ohio Railroad right-of-way, the Site is bordered by the abandoned Erie and Lackawanna Railroad right-of-way, and the active

portion of the Griffith Municipal Landfill. North of the Chesapeake and Ohio right-of-way, the Site is bordered on the west by wetland areas. The northern boundary of the Site is formed by the Grand Trunk Railroad right-of-way.

7.1.3.1.2 Physical Setting

The Site is located in northwestern Indiana in the Calumet Lacustrine Plain, a subdivision of the Northern Moraine and Lake Region of Hartke, et. al (1975). The Calumet Lacustrine Plain represents a portion of the lake bed of glacial Lake Chicago. The landscape is generally low-lying and exhibits little relief. In the immediate Site vicinity, surface elevations range between 650 and 630 ft. MSL. The lower surface elevations are associated with the wetlands located to the west and south of the Site, while the higher elevations represent the relict sand dunes found east of the Site.

The geologic and hydrogeologic setting of the Site is presented in detail in Section 4 of this report. In general, the geologic setting of the Site consists of approximately 130 ft of unconsolidated glacial deposits overlying bedrock. Three geologic units have been identified within the glacial deposits. These units are: an upper sand and gravel unit, an intermediate silty clay unit, and a lower sand and gravel unit. Bedrock was not encountered in any of the borings performed for the RI.

The upper sand and gravel unit forms the uppermost aquifer at the Site. In the Site monitoring wells, the thickness of this unit ranges from 13 to 32 ft, and averages 17 ft. The upper aquifer exists under water table conditions at the Site, and is directly influenced by precipitation patterns. Four dominant hydraulic controls have been recognized for the uppermost aquifer. These controls include: (1) the regional gradient, (2) discharge to drainage ditches, (3) dewatering activities at the active landfill, and (4) recharge to the aquifer, which occurs mainly in the cleared and filled areas. Potentiometric maps illustrating flow within the upper aquifer are presented in Figures 4-17, 4-18, and 4-21.

The intermediate silty clay unit forms a confining layer between the upper aquifer and the lower sand and gravel unit (lower aquifer). The silty clay ranges in thickness from about 2.5 ft to 18 ft. This confining layer was found to be the thinnest in the northwestern portion of the Site.

The full thickness of the lower sand and gravel unit (lower aquifer) was not penetrated in any of the borings performed for the RI. Drillers' logs for water wells in the Site vicinity indicate that the lower aquifer can be in excess of 50 ft thick. Based on monitoring wells installed during the RI, the flow direction in the lower aquifer is to the north.

Approximately 72 private wells were identified in the Site vicinity during the RI. Figure 2-7 illustrates the location of the wells. Complete information on well depth and aquifers screened were not available for all of the wells. The available information has been summarized in Table 2-6 and Figure 2-7.

The majority of the private wells in the immediate Site vicinity which are used for drinking water purposes are located to the east and northeast of the Site. These wells draw water from the lower aquifer. Several wells in the upper aquifer were identified near the Site, these wells are generally not used for drinking water supplies, but were known to be used as drinking water supply wells as recently as five years ago by some area residents located one-half mile north (upgradient) of the Site. Figure 4-13 illustrates the locations of the private wells identified near the Site with respect to the flow direction in the lower aquifer.

7.1.3.1.3 Zoning and Surrounding Land Uses

Zoning in the immediate vicinity of the Site is primarily industrial (Figure 7-2). The areas adjacent to the Site on the north, east, and southeast are zoned either industrial or light industrial. Areas to the west and southwest of the Site are zoned one-family residential. No zoning changes are planned for the Site area.

In keeping with the current zoning, the following land uses are observed in the immediate Site vicinity. In the following discussion, land uses are described in a clockwise fashion around the Site, beginning at the northeast corner.

Northeast of the intersection of Colfax Avenue and the Grand Trunk Railroad right-of-way is a park, Oak Ridge Prairie. Immediately east of the Site fenced compound and north of the Chesapeake and Ohio Railroad right-of-way, the land is undeveloped. On the east side of Colfax Avenue and south of the Chesapeake and Ohio Railroad right-of-way (east of the Off-Site Containment Area) are several small businesses, including an auto repair shop, a welding shop, and a security dog business. East of the Site, along the north side of Reder Road, are several single family residences. Along the south side of Reder Road in this same area are several small businesses, including a trucking firm, an auto repair shop, and an environmental clean-up contracting firm. South of the intersection of Reder Road and Colfax Avenue (Arbogast), on Arbogast, are a private residence and a small industrial building.

To the west and southwest of the Site, west of the abandoned Erie and Lackawanna Railroad right-of-way, are vacant land and a residential development. The residential area is separated from the Site by the active portions of the Griffith Municipal Landfill.

North of the Grand Trunk Railroad right-of-way, along the northern boundary of the Site, the land is primarily vacant. Further to the north, along Main Street, are small businesses and an industrial park.

7.1.3.1.4 Distance to Nearest Receptors

The nearest residence to the Site is located at 1002 Reder Road, approximately 150 ft east of the Off-Site Containment Area. Other residences within about 500 ft of the southeastern property boundary include 1009 Reder Road, 1033 Reder Road, 1043 Reder Road, and 945 South Arbogast. The nearest potential receptors east of the Site are the employees of the businesses located approximately 100 to 200 ft east of the Off-Site Containment Area, along the east side of Colfax Avenue. To the south and west of the Site, the nearest potential receptors are the employees of the Griffith Municipal Landfill, and the occupants of the residential development approximately 800 ft west of the Site boundary. To the north, the nearest potential receptors are occupants of the industrial park and small businesses along Main Street (approximately 1000 to 2000 ft north of the Site boundary).

7.1.3.1.5 Population Information

The most recent census for which data was available on individual census tracts was the 1980 census. Based on 1980 census data (as of this writing, 1990 census data was not available), 17,026 people live in the Town of Griffith. In the census tracts of other communities within a two mile radius of the Site, 15,423 persons were identified in the town of Highland, 18,149 in the town of Merrillville, 1,423 in the town of Schererville, and 8,084 in unincorporated Lake County.

The median age of persons identified in the Griffith census tracts was 27.7 to 32.8 years. The median age in the Highland tracts bordering the Site area was 28 to 30.7 years. The median age in the Merrillville tract and the Schererville tract, respectively, was 34.7 and 24.8 years. In the unincorporated areas of Lake County bordering the Site, the median age was 30.1.

7.1.3.2 Exposure Pathway Analysis

A chemical exposure pathway describes the route taken by a chemical from its source in the environment, to contact with receptors. As such, each exposure pathway must include the following elements:

- A source and mechanism of chemical release to the environment;
- An environmental transport medium (e.g., air, groundwater) for the released chemical;
- A point of potential human contact with the contaminated medium (referred to as the exposure point); and
- Receptor contact (e.g., ingestion of contaminated groundwater).

In general, exposure may occur when contaminants migrate from the Site to an exposure point (i.e., a location where receptors can come into contact with contaminants) or when a receptor comes into direct contact with waste or contaminated media at the Site. An exposure pathway is complete (i.e., exposure occurs) if there is a way for the receptor to take in contaminants through ingestion, inhalation, or dermal absorption of contaminated media or waste.

7.1.3.3 Contaminant Sources

As a result of waste disposal practices at the Site, sources of potential contaminant release were considered to exist as:

- Buried wastes;
- Waste constituents that have sorbed to soil in the saturated and unsaturated zone; and
- Waste constituents occupying soil pore space in the saturated and unsaturated zone.

These sources are characteristic of the nine areas determined to be contaminated (Page 7-3).

7.1.3.4 Contaminant Migration

The distribution of chemicals associated with on-Site waste disposal indicate migration through environmental media is occurring. In general, the migration of Site contaminants will be controlled by physical conditions at the Site and the inherent physical and chemical properties of the migrating compounds.

Because the mechanism of release and transport of a chemical are important elements in an exposure pathway, the physical and chemical properties of each chemical were used to approximate its general behavior in the environment. The physical and chemical properties of the chemicals of potential concern have been obtained from the literature as appropriate, and approximated, if necessary for use in risk assessment. A list of these properties for the chemicals of potential concern is provided in Table 7-14.

Potential mechanisms for contaminant release at the Site include:

- Leaching of contaminants into the groundwater and downgradient migration;
- Volatilization of subsurface and surface contaminants from the Site to the ambient air;
- Generation of fugitive dusts from exposed soil areas;
- Groundwater discharge to nearby wetlands; and
- Surface runoff of contaminants from the Site.

As a result of wastes disposed, it is evident that surface water and sediments, surface and subsurface soils, upper and lower groundwater aquifers, and the ambient air are media impacted by contamination at and near the Site. Sections 5 and 6 of the RI Report contain information regarding contaminant distribution and the fate and migration of chemicals at the Site. Each of these mechanisms for contaminant release at the Site are discussed in Section 6.

7.1.3.5 Selection of Exposure Pathways For Risk Assessment

The potential exposure pathways at the Site were based on the potential contaminant migration pathways and the Site setting. These potential exposure pathways were evaluated to determine whether they are complete or have the potential to be complete in the future. Current use of the Site and adjacent land and potential future land uses were considered in the analysis.

7.1.3.5.1 Current Land Use

Current land use of the Site and surrounding area was based primarily on information gathered during Site visits. Other sources of information that assisted in this evaluation included zoning maps, census information, and aerial photographs. After defining the current land use at the Site, a determination of human activities and behavioral patterns was made. This approach was based on "common sense" and not on any specific data sources, but rather on a general understanding of the types of activities that may be associated with the land use.

Several potential exposure pathways were assumed to exist under the current land use scenario. These exposure pathways are summarized below and in Table 7-15.

Off-Site Residents

- Incidental ingestion of contaminated water from the upper aquifer (children swimming in a pool or playing in lawn sprinklers).
- Dermal absorption of contaminated water from the upper aquifer (children swimming in a pool or playing in lawn sprinklers).
- Ingestion of contaminated water from the lower aquifer.
- Dermal absorption of contaminated water from the lower aquifer while bathing.

- Inhalation of VOCs released from water from the lower aquifer during its household use (e.g., bathing, showering).
- Inhalation of VOC emissions released from subsurface soil contamination.
- Inhalation of contaminants entrained by fugitive dusts emanating from surface contamination at Kapica-Pazmey.

Adolescents Playing On-Site (Trespassing)

- Inhalation of volatiles released from subsurface soils at the Site.
- Inhalation of fugitive dusts released from surface soil contamination at Kapica-Pazmey.
- Incidental ingestion of contaminated surface soils at Kapica-Pazmey.
- Dermal contact with contaminated surface soils at Kapica-Pazmey.
- Incidental ingestion of contaminated surface water from wetlands and drainage ditches.
- Dermal contact with contaminated surface water from wetlands and drainage ditches.
- Incidental ingestion of contaminated sediments from wetlands and drainage ditches.
- Dermal contact with contaminated sediments from wetlands and drainage ditches.

On-Site Workers at the Site

- Inhalation of volatiles released from subsurface soil contamination at the Site.
- Inhalation of fugitive dusts migrating from Kapica-Pazmey.

In addition to the exposures that exist for each population as described above, it is possible that a trespasser may also be an off-Site resident, and on-Site workers may be an off-Site resident. Thus, while pathways have been combined for each individual population, populations could also be combined, as appropriate (e.g., off-Site resident and trespasser) to evaluate the maximum exposure of a population that is reasonably expected to occur at the Site. The following sections discuss the potential for exposure to receptors through specific environmental media, and areas, as appropriate, for current land use conditions.

7.1.3.5.1.1 Off-Site Residents (Including Trespassers)

Residential dwellings exist near the boundaries of the Site. The current land use takes into account that there are residents who have access now and will have access in the future to contaminated areas of the Site. This access may actually increase in future years, because of the possibility that current ownership may change, and land access will be less restrictive. Given that the Baseline Risk Assessment assumes the "no-action" alternative (i.e., the risks to human health which may occur at anytime in the future if U.S. EPA does not require some remediation of the Site), it is plausible that off-Site residents, including trespassers, may be exposed to contaminants at the Site.

7.1.3.5.1.1.1 Potential Exposure Through Groundwater Use

Two groundwater aquifers have been identified at the Site during the RI; an upper aquifer and a lower aquifer. A continuous clay layer was documented across the Site effectively separating the two systems (see previous sections on geology and hydrogeology of the Site for details). The lower aquifer is used for drinking water purposes; however, the upper aquifer is not classified for drinking water use. In fact, a survey of homes adjacent to the Site performed during the RI indicated that private wells exist in both aquifers; however, the upper aquifer is reportedly only used for non-potable purposes (e.g., lawn care, car washing). However, some persons located one-half mile north (upgradient) of the Site reportedly had used the upper aquifer for drinking water purposes as recently as five years ago. No private wells screened in the upper aquifer were sampled during the RI; lower aquifer private wells were sampled (see Figure 4-13 for locations of private wells).

Local officials (City of Griffith - Office of Public Works) indicated that there is no ordinance in place which would restrict the placement of wells for new construction. Most City residents use the City water supply system for drinking water; some residents do use private wells screened in the lower aquifer. There are no municipal wells used locally by the City of Griffith. However, a pump station used to supply water to City residents is located at 45th Street and Glenwood in Griffith. The source of this water is the Gary-Hobart Company. The pump station supplies three overhead storage tanks for distribution.

7.1.3.5.1.1.1 Upper Aquifer

The groundwater flow pattern in the upper aquifer has been shown to be confined to within a few hundred feet of the Site boundary. Some homes at greater distances from the Site were found to maintain wells in the upper aquifer and reportedly use the water for lawn care and other non-potable uses. If contaminated groundwater were to migrate to these off-Site wells, exposure might be possible while gardening or if children were to play in the water.

Groundwater flow in the upper aquifer is controlled by several factors as discussed in previous sections of this RI Report. The flow of groundwater in the upper aquifer appears to be diverted towards an excavation near the active landfill used to de-water the landfill, and by the wetlands which surround the Site. The fire pond acts as an injection point creating a groundwater high at the Site which influences flow.

Since the groundwater flow paths are controlled primarily by water injection at the firepond and dewatering at the landfill, changes in either of these activities could result in changed flow paths and therefore, the potential might exist for contaminants in the upper aquifer to migrate to off-Site locations, presenting an exposure potential to residents who use private wells screened in the upper aquifer near the Site. Groundwater modeling was not performed to predict the fate and transport of contaminants in groundwater; therefore, it was assumed that on-Site groundwater chemical concentrations may be equivalent to off-Site concentrations, in time, if not mitigated.

If no action were taken at the Site to mitigate contaminant release to groundwater, and the plume were to reach private wells in the upper aquifer, residents could be exposed to contaminants in the water. For purposes of this risk assessment, a child, age 5-15 years old, using the water for play (using water in a swimming pool), was selected to represent a "worst case" population among off-Site users of the upper aquifer (this is consistent with the intent of the current guidance in defining the maximum exposure that is reasonably expected to occur). Children could be exposed to contaminants in water from the upper aquifer through the following exposure pathways:

- Incidental ingestion of water while swimming in a pool containing contaminated groundwater from the upper aquifer; and

- Dermal exposure while swimming.

The Griffith Municipal Landfill was also evaluated separately for its potential impact on groundwater. There is evidence that the landfill is generating leachate. The leachate is being controlled by a collection system (de-watering excavation). Monitoring wells located in the upper aquifer, and down-gradient of the landfill appear to indicate the collection system has been effective in limiting release of contaminants (in leachate) to the upper aquifer.

Based on the RI, there is no evidence that release of contaminants associated with the landfill, is occurring, or has occurred in the past. Contaminant release from the landfill, based on cessation of the collection system, has been modeled to evaluate potential future land use exposures (see Section 7.1.3.5.2.1.1).

7.1.3.5.1.1.1.2 Lower Aquifer

Eight private wells located in the deep aquifer were analyzed during the RI and had no detectable levels of contamination (two additional wells were sampled in January 1991). Both the Site and landfill facilities maintain wells in the lower aquifer; the well at the landfill facility is used for drinking water; the wells at the Site are used for industrial processes and for drinking water.

There appears to be a substantial amount of retardation of contaminants migrating vertically from the upper aquifer to the lower aquifer due to the confining clay layer. While the confining clay layer was found to be only 2.5 ft thick in one limited area, generally it is greater than 6 ft thick across the Site. The clay layer provides an effective separation between the two aquifers because of its high organic carbon content and low permeability. The potential for contaminant exposure via the lower aquifer is considered to be low. Contamination was found in the lower aquifer at monitoring well MW9D, but was not found at any other lower aquifer monitoring wells, indicating that the contamination is limited and has not extended off-Site. For the purposes of risk assessment, contaminants detected in the lower aquifer were assumed to migrate at their present concentrations to off-Site locations where exposure might occur. Exposure pathways include:

- Ingestion of water;
- Dermal absorption of contaminants from water during bathing; and
- Inhalation of the VOCs released from water during its household use (e.g., showering, bathing, etc.).

7.1.3.5.1.1.2 Potential Exposure to VOCs in Ambient Air

Contaminants can be released to the air through volatilization. Numerous VOCs have been detected in various Site media from which volatilization could occur. The majority of volatiles are located at discrete areas of the Site. These areas include the on-Site containment area, off-Site containment area, Kapica-Pazmey, and the still bottoms and treatment lagoon area. Each of these areas, with the exception of Kapica-Pazmey, have been covered with clean material. Although VOCs are also detected in other media (e.g., groundwater), it is expected that the greatest quantity of release of VOCs to air would come from the subsurface soils from the areas just described.

Several factors may reduce the significance of VOC releases to ambient air. It is believed that most of the VOCs are present at the water table. The soil moisture in this zone may serve to inhibit the release of VOCs. Once released, the VOCs would be diluted with ambient air.

The quantity of VOCs emanating from the contaminated subsurface soils is expected to be low compared to that from the Site. No air samples were taken in the field during the RI because of the difficulty in distinguishing air pollutant sources at the Site from anthropogenic background. However, it should be recognized that volatiles released from Site pollution may pose potential inhalation exposure (proportionately) to on-Site as well as off-Site populations residing near the Site and to children who may play (trespass) on-Site. Predicting the amount of exposure quantitatively for this risk assessment required estimating potential emissions from the subsurface soils and using a dispersion model to obtain on-Site and downwind VOC concentrations.

7.1.3.5.1.1.3 Potential Exposure to Contaminants Via Fugitive Dust

The potential for contaminants to be released to air via fugitive dust is expected to occur only at the Kapica-Pazmey area. In this area, there are unvegetated areas of surface soil contamination where fugitive dust generation from wind erosion is possible. The bare soil is visibly contaminated at this location and based on particle size analysis, soil particles are conducive to such a release. Dust generation was observed in this area during the RI.

There is little or no potential for fugitive dust release from other areas where contamination exists. The on-Site containment area, off-Site containment area, and still bottoms and treatment lagoon area are covered with clean material, effectively eliminating the potential generation of contaminated fugitive dust. The still bottoms and treatment lagoon area is covered by construction and the off-Site containment area is covered by dense vegetation.

The greatest potential for inhalation of contaminated dusts would be by children playing (trespassing) at the Kapica-Pazmey area. However, contaminants entrained on soil particles in air could also migrate to off-Site residences near the Site where they might be inhaled by receptors (residents).

7.1.3.5.1.1.4 Potential Exposure Via Direct Contact with Contaminated Soils

Surface soil contamination is evident at Kapica-Pazmey where potential exposure via direct contact is considered to be plausible for adolescents trespassing on-Site. Subsurface contamination beneath clean cover material exists at other locations on-Site but does not represent a direct contact exposure potential under current conditions.

The source area at Kapica-Pazmey is an open area adjacent to Site buildings. The open area is visually contaminated (see Table 7-7 for analytical results) and is unvegetated. Access to the property is partially restricted by fences and buildings but, the area is not completely restricted.

The potential for exposure to contaminated soils under current conditions is plausible only for soils located at the surface. Contact with soils below ground surface would require excavation (digging) and is not likely to occur on a regular basis. Risks to subsurface soils were considered under the future land use scenario.

The most plausible population which may contact surface soils in these areas is considered to be adolescents who may play (trespass) on the Site. To assess potential health risks associated with contaminated surface soils, contaminant exposure was quantified by assuming adolescents regularly play at the Kapica-Pazmey location. Exposure routes considered included incidental ingestion and dermal absorption.

7.1.3.5.1.1.5 Potential Exposure Via Contact with Surface Water and Sediments

Wetlands are found on all sides of the Site. In addition there are drainage ditches near the Site which transport overland runoff in the area. Surface water and sediment samples (see Tables 7-9 and 7-10 for a summary of analytical results) collected and analyzed from these Site features indicate the presence of contamination.

Portions of the groundwater table discharge from the upper aquifer into the wetlands and surface water surrounding the Site. It is possible that if no action is taken, groundwater with increasing contaminant levels would discharge to the wetlands. If this were to occur, people and wildlife might be exposed to contamination in these media currently and in the future.

To assess the health risks associated with contamination detected in surface water and sediments, adolescents were assumed to play (trespass) on-Site and become exposed to these media on a regular basis. Exposure was assumed to be plausible through incidental ingestion and dermal contact.

It is unknown whether hunting activities take place on-Site. However, it is expected that if hunting does occur, this is a small potential user group. The Site is surrounded by residences, commercial businesses, and industry making hunting an impractical matter.

The surface waters on-Site are not indicative of habitats for major sport fishing populations. Thus, fishing appears to be inherently limited by the physical makeup of the Site.

It is reasonable to conclude that terrestrial and aquatic organisms taken from the Site would not constitute a major source of food for human consumption. Potential exposure to chemical contaminants via ingestion of aquatic species or wildlife was not evaluated due to the lack of a defined user group and the reasonable assumption of limited potential for exposure.

7.1.3.5.1.2 On-Site Workers at the Site

ACS continues to maintain its operations and thus, employees of the Site represent a population potentially exposed to Site contamination under current conditions. The Site has effective access limitations and only authorized personnel are allowed on the property.

There are no apparent direct contact exposures to surface water or soils at the Site. This area of the Site has been covered by clean fill material, effectively eliminating the potential for direct contact with buried materials, particularly in the area of on-Site containment.

There is only one surface water body location on the Site. This location was analyzed and found to contain relatively low levels of contaminants. This lagoon is actively used for Site processes, and workers may encounter the lagoon. However, working activities near the lagoon were considered to be voluntary, and associated with job requirements. Site workers were assumed to be trained in their job functions, and have an understanding of potential worker hazards. The Occupational Safety and Health Act (OSHA) requires compliance with safety and hygiene standards to reduce potential risks to these employees. Site worker exposure to the lagoon was not evaluated in the Baseline Risk Assessment.

The Site maintains four groundwater wells. These wells are used for industrial purposes, as well as for drinking water. All four of these wells are installed in bedrock at a depth greater than 300 ft. The RI has focused on evaluating the upper aquifer and the lower sand and gravel aquifer, separate from the bedrock. The bedrock

aquifer has not been identified as a concern in the RI, nor has it been defined as being Site-related. Analysis of one of the four wells indicated no contamination. The bedrock aquifer was not considered further in the risk assessment.

7.1.3.5.1.2.1 Potential Exposure to Contaminants Via Inhalation of VOCs

The most apparent exposure to workers at the Site would be via inhalation of gases/vapors released from their operations; this is apparent based on observation during Site visits. The VOC releases emanating from buried materials on the Site (on-Site containment area, and still bottoms and treatment lagoon area) are in addition to that of the Site operations. To assess health risks to Site workers due to VOC releases to ambient air, only those releases associated with the buried contamination on and near the Site were considered.

7.1.3.5.1.2.2 Potential Exposure to Contaminants Via Fugitive Dusts

As described previously, the Kapica-Pazmey area has exposed contamination at the surface. Site workers may be exposed via inhalation to downwind concentrations of contaminated dusts emanating from the Kapica-Pazmey area.

7.1.3.5.2 Future Land Use

There are no hard-and-fast rules by which to determine alternate future land use. To the extent the information was available and applicable, City and County projections of future land use, census projections, and information regarding land use trends were used to assist in the determination of future land use for this risk assessment. While these sources may provide useful information, they cannot always be interpreted as providing proof that a certain land use will or will not occur. Thus, much of the interpretation for determination of the future use scenario for this risk assessment was based on professional judgment.

The Zoning District Map (Figure 7-2) for the Town of Griffith indicates the Site is zoned general industrial. However, there is residential zoning adjacent to the Site and some residences exist within the industrial zoned areas. Although future trends regarding development of the area are not known with certainty, it may be possible that the Site or areas near the Site could be developed for residential use (i.e., the

probability that the Site will support residential land use in the future is not so exceedingly small to preclude using this scenario for this assessment). The residential use scenario was selected based on concurrence with the U.S. EPA Region V RPM, and Technical Support Group.

The likelihood of residential development at and near the Site in the future is supported primarily by the presence of residences currently near the Site. In addition, because the Baseline Risk Assessment must evaluate the Site on the basis that no action is taken to mitigate the Site and no restrictions and/or institutional controls are placed on future use of the Site, the residential pathway seemed plausible for risk assessment. An alternate future use is for industrial purposes. The potential exposure pathways associated with future land use of the Site for industrial purposes has been included in this risk assessment under the current land use scenario. An evaluation of exposure pathways based on potential future land use changes is summarized in Table 7-15 and discussed below.

Hypothetical Resident Living On-Site

- Ingestion of contaminated groundwater from the lower or upper aquifer.
- Dermal absorption of contaminated groundwater from the lower or upper aquifer.
- Inhalation of VOCs released from water from the lower or upper aquifer during its household use (e.g., showering, bathing).
- Dermal absorption and incidental ingestion of contaminants adsorbed onto sediments and soils.
- Dermal absorption and incidental ingestion of contaminants detected in surface water.
- Inhalation of volatiles released to ambient air.

7.1.3.5.2.1 Hypothetical Resident Living On-Site

7.1.3.5.2.1.1 Potential Exposures Via Groundwater

As has been previously stated, there are two groundwater aquifers at the Site; upper and lower. For the purpose of this risk assessment, it was assumed that a residential well could be screened in either of the aquifers and used as a drinking water source.

Without remedial action for Site clean-up, nor institutional restrictions or other limitations, as specified by guidance for the Baseline Risk Assessment, risks have been quantified for residential use of either aquifer for drinking water purposes. The routes of contaminant intake evaluated include ingestion and dermal absorption of groundwater, and inhalation of VOCs released from groundwater during its household use.

Contaminant concentrations were assumed to remain at their present levels when performing the calculations to estimate the amount of exposure under future land use conditions. This assumption may over- or under-estimate the exposure. Using steady-state conditions does not account for substantial future releases of unmitigated source materials to groundwater that may occur over time, nor does it account for source depletion and attenuation of materials through environmental fate and transport processes. It is not known with certainty the resultant (future) groundwater concentrations due to these potential (collective) impacts.

In addition to the Site-specific geologic and hydrogeologic conditions, and extraneous groundwater influences (as previously discussed in the RI Report), many chemical and physical properties affect chemical transport and fate in groundwater. Some of the more important mechanisms include leaching from the surface, advection (infiltration, flow through the unsaturated zone and flow with groundwater), dispersion, sorption (adsorption, desorption, and ion exchange), biological degradation, hydrolysis, oxidation, reduction, complexation, dissolution, and precipitation. In accordance with current U.S. EPA guidance documents, current concentrations can be used to represent future concentrations assuming a steady-state condition when groundwater modeling is not used.

For directly assessing the potential impact of the Griffith Municipal Landfill on groundwater, the collection/de-watering system was assumed to be stopped, and a model was used to determine the potential release of contaminants in leachate to groundwater. This evaluation was made to assess the potential risks to a hypothetical future use residence, with a private well, located immediately adjacent to, and downgradient from the landfill.

7.1.3.5.2.1.2 Potential Exposure Via Contact with Contaminated Soils

Little contamination exists at ground surface at the Site. In general, the contaminants have been buried below ground. Therefore, exposure to soils is limited unless the subsurface soils are excavated and brought to the surface where exposure may be possible. Exposures were quantified for subsurface soils being unearthed and brought to the surface consistent with the "no-action" alternative, and future land use for residential development. The contaminated subsurface soils were assumed to be excavated during hypothetical development of residences on-Site, and used as fill material and cover material in yards, gardens, and playgrounds. This exposure pathway is highly subjective; however, using such a pathway may be more important as it relates to the feasibility study in determining which chemicals in subsurface materials may require evaluation in the detailed analysis of alternatives.

The analytical results for subsurface and surface soils have been averaged together to account for mixing of soils, where appropriate, to arrive at exposure point concentrations. It should be recognized that there are degradative processes which would act to reduce contamination over time. However, these processes are complex and their impact has not been predicted for risk assessment; exposure point concentrations assume steady-state conditions.

7.1.3.5.2.1.3 Potential Exposure Via Contact With Contaminated Surface Water and Sediments

For future land use considerations, the wetlands and drainageways were assumed to be protected, and remain unchanged from current conditions. Contaminants were also assumed to reflect steady-state conditions. This assumption appeared reasonable since the sources, under the no action alternative, may continue to contribute to surface water and sediment contamination. Therefore, contact with surface water and sediments would be the same as described for the current land use scenario. On-Site residents were assumed to have occasional contact with contaminated surface water and sediments through the dermal absorption route and incidental ingestion.

7.1.3.5.2.1.4 Potential Exposure Via Inhalation of Contaminants Released to Air

Fugitive dust generation and VOCs emanating from contaminated areas are the two potential release routes to air.

Under future land use considerations, it was assumed that fugitive dust generation would be effectively minimized by conditions evident in an urban setting. That is, unearthed contaminated soils brought to the surface, would be covered by vegetation, building construction, roadways, and other ground cover features. These features, in essence, reduce the potential for wind and/or mechanical erosion forces necessary to generate dusts. VOC release could potentially occur through the soil cover into the ambient air. This pathway is similar to the current land use pathway where VOCs in subsurface soil are released from the source through the ground cover to the ambient air. The mechanism for VOC release would still exist and may be enhanced under these circumstances presenting potential exposure to on-Site residents via inhalation of VOCs.

7.1.3.6 Quantification of Human Exposure Estimates

Exposure is defined as the contact of an organism with a chemical or physical agent. In this assessment, exposure (intake or dose) is normalized for time and body weight and is expressed as mg chemical/kg body weight-day (mg/kg-d). Five factors are used to estimate intake; exposure frequency, exposure duration, contact rate, exposure point concentrations, and body weight. This section summarizes the exposure factors used in this assessment. The methodology (equations) for calculating estimates of human exposure is provided in Appendix T.

An additional term in the dose estimate equation is "averaging time," which normalizes the dose over a specified period of time. For chemicals which are potential carcinogens, dose estimates are normalized over a 70 year lifetime to allow comparison with toxicology information which is generated from studies in which the test species is exposed to the chemical over the majority of its lifetime. Dose estimates which are used to assess the non-cancer effects of chemicals are normalized over the period of exposure.

Recently published national statistics on the number of years spent by an individual in one residence indicate that the average number of years spent at a single residence is 9 and the 90th percentile figure is 30 years (U.S. EPA, 1989). This assessment uses the 90th percentile figure to represent the period of exposure for many of the exposures assumed to occur at and near the Site. Thus, the averaging time for carcinogens versus noncarcinogens is 70 years and 30 years, respectively. There are instances where the exposure period is less than 30 years (e.g., child swimming - 10 years, adolescent playing on-Site - 10 years). In these cases, the averaging time for carcinogens is still 70 years; however, non-cancer effects of chemicals are normalized over 10 years.

Levels of exposure are quantified to allow comparison with exposure levels corresponding to adverse health effects. Estimates of contaminant exposure can be derived using the following general equation:

$$\begin{array}{ccccccc} \text{Contaminant} & & & & & & \\ \text{Dose} & = & \text{Chemical} & \times & \text{Contact} & \times & \frac{1}{\text{Body Weight}} \\ \text{Estimate} & & \text{Concentration} & & \text{Rate} & & \times \frac{1}{\text{Averaging Time}} \\ & & & & \text{Exposure Frequency} & & \\ & & & & \text{and Duration} & & \end{array}$$

The contaminant dose estimate may represent either an "administered" or "absorbed" dose. An administered dose refers to a contaminant exposure which occurs at an exchange boundary of an organism. For example, exposure via ingestion (drinking groundwater) is based on delivery of the contaminant to the gastrointestinal tract. Equations which estimate doses for some exposures incorporate a variable which accounts for absorption of the contaminant across the exchange boundary into the blood stream. This estimate is referred to as an "absorbed dose estimate." The distinction between administered and absorbed dose estimates is necessary for proper comparison with toxicity information, as is further described in the Toxicity Assessment.

The most recent EPA guidance states that actions at Superfund sites should be based on an estimate of the "reasonable maximum exposure" expected to occur under both current and future land use conditions. The reasonable maximum exposure is defined as the "highest exposure that is reasonably expected to occur at a site" (U.S. EPA, 1989). The intent of the reasonable maximum exposure is to estimate a conservative

exposure case (i.e., well above the average case) that is still within the range of possibilities. Each exposure factor has a range of possible values. In accordance with the guidance, this assessment has used values for the exposure factors that result in an estimate of the reasonable maximum exposure.

7.1.3.6.1 Groundwater/Surface Water Exposures

Exposure to contaminants through the use of groundwater as a water supply source from either the lower or upper aquifer was estimated for the ingestion, dermal absorption, and inhalation routes of exposure. The exposure assumptions used to describe groundwater use are summarized for individual populations in Appendix T. Intake equations are also presented in this Appendix.

The principles used to calculate groundwater dose estimates were used to evaluate exposure to surface water; however, the parameters used to calculate surface water exposure are different. Assumptions applied to the surface water exposure pathways are contained in Appendix T for each population.

Some of the more important intake assumptions are highlighted below for each exposure route.

7.1.3.6.1.1 Ingestion

This assessment follows the U.S. EPA's standard set of exposure assumptions to describe exposure through ingestion of drinking water (U.S. EPA, 1989). These assumptions include an ingestion rate of 2 liters per day for drinking water.

An ingestion rate of 0.05 L/hr was used for incidental ingestion of water while swimming (2.6 hours/day, 52 days/year), and 0.005 L/hr for incidental ingestion of surface water for children assumed to play near wetlands and drainage ways (3 hours/day, 52 days/year).

7.1.3.6.1.2 Dermal Absorption

Exposure through dermal absorption is a function of more variables than ingestion, and there is no standard set of exposure assumptions. The assumptions used in this assessment are based on recent EPA guidance and professional judgment.

exposure case (i.e., well above the average case) that is still within the range of possibilities. Each exposure factor has a range of possible values. In accordance with the guidance, this assessment has used values for the exposure factors that result in an estimate of the reasonable maximum exposure.

7.1.3.6.1 Groundwater/Surface Water Exposures

Exposure to contaminants through the use of groundwater as a water supply source from either the lower or upper aquifer was estimated for the ingestion, dermal absorption, and inhalation routes of exposure. The exposure assumptions used to describe groundwater use are summarized for individual populations in Appendix T. Intake equations are also presented in this Appendix.

The principles used to calculate groundwater dose estimates were used to evaluate exposure to surface water; however, the parameters used to calculate surface water exposure are different. Assumptions applied to the surface water exposure pathways are contained in Appendix T for each population.

Some of the more important intake assumptions are highlighted below for each exposure route.

7.1.3.6.1.1 Ingestion

This assessment follows the U.S. EPA's standard set of exposure assumptions to describe exposure through ingestion of drinking water (U.S. EPA, 1989). These assumptions include an ingestion rate of 2 liters per day for drinking water.

An ingestion rate of 0.05 L/hr was used for incidental ingestion of water while swimming (2.6 hours/day, 52 days/year), and 0.005 L/hr for incidental ingestion of surface water for children assumed to play near wetlands and drainage ways (3 hours/day, 52 days/year).

7.1.3.6.1.2 Dermal Absorption

Exposure through dermal absorption is a function of more variables than ingestion, and there is no standard set of exposure assumptions. The assumptions used in this assessment are based on recent EPA guidance and professional judgment.

Dermal absorption exposure is a function of permeability of the skin, surface area exposed, and length of exposure. Chemical-specific permeability constants (PC) (which approximate the rate of chemical movement across the skin) are not available for all contaminants. Where they are not available for VOCs, this assessment assumes that contaminants penetrate the skin at the same rate as toluene (U.S. EPA directive) when toluene is present. When toluene is not present, the chemical of concern with the next greatest permeability potential was used. The PC for water was used as a default value for metals, and the PC for 2-butanone was used as a default value for semi-volatiles (U.S. EPA directive). The assessment assumes that dermal absorption of water occurs through the use of groundwater while showering, when children swim in pools filled with contaminated groundwater, and when children play on-Site and become exposed to surface water.

7.1.3.6.1.3 Inhalation

Inhalation of VOCs released from drinking water to household air was approximated using a draft methodology supplied by the U.S. EPA Exposure Assessment Group, Office of Health and Environmental Assessment ("Screening Method for Estimating Inhalation Exposure to Volatile Chemicals from Domestic Water"). The procedure has evolved from research performed by Julian Andelman, University of Pittsburgh. Appendix T contains the formula for deriving concentrations of chemicals released to air while showering. Appendix Z contains the methods used to arrive at a chemical concentration in air as a result of volatilization. The concentration estimate was then applied to standard methods for calculating daily intake.

Inhalation of volatiles released from contaminated water in a swimming pool or from surface water was considered negligible and not quantified in this risk assessment.

7.1.3.6.2 Soil/Sediment Contact Exposures

Exposure to contaminants in soils and sediments were assumed to occur through dermal absorption and incidental ingestion. Soil and sediment contact impacts populations considered in both current and future land use scenarios (i.e., trespassers, hypothetical on-Site residents). The exposure variables have been adjusted accordingly based on the population exposed. For specific information regarding the exposure

variables associated with each population and route of exposure, refer to Appendix T. These tables also contain the equations used to calculate intake. Some of the more important exposure assumptions used to calculate intake are provided below.

7.1.3.6.2.1 Incidental Ingestion

Standard assumptions were used to calculate incidental ingestion of soil/sediment. Contact is assumed to occur 6 months per year because snow cover and/or frozen ground is assumed to prevail 6 months per year. A standard ingestion rate of 100 mg soil/day was used.

7.1.3.6.2.2 Dermal Absorption

As with dermal absorption of water, there is no standard set of exposure assumptions for dermal absorption from soil or sediment. Dermal absorption of soil/sediment is a function of permeability of the skin, surface area exposed, soil/sediment deposition, and length of exposure. Estimates of the rate of absorption of chemicals from soil/sediment are not available for many contaminants so the method stipulated in U.S. EPA guidance was used. Exposure through dermal absorption from soil/sediment was calculated using specific dermal absorption factors when available, otherwise an absorption factor of 30% was used for organic compounds. The organic value was based on information obtained from ECAO for PAHs. Metals do not readily absorb, thus 1% was assumed to be a reasonable estimate of absorption for these elements.

7.1.3.6.3 Air Exposures

7.1.3.6.3.1 Inhalation

Subsurface contamination at several areas of the Site contain high concentrations of VOCs, potentially providing a continuous source of releases to the air. Climatic conditions were assumed to limit volatilization to 6 months of the year (absent or negligible during the winter). In addition, fugitive dust generation is anticipated at the Kapica-Pazmey area. Both of these mechanisms of contaminant release to the ambient air may pose an inhalation hazard and have been included for risk assessment. On-Site and off-Site exposures have been evaluated for current and future land use populations, as appropriate.

Standard assumptions have been applied to the inhalation pathway when available, while professional judgment was utilized for some of the parameters. Exposure assumptions and the equations to calculate intakes for the air pathway for each population are listed in Appendix T.

7.1.3.7 Exposure Point Concentrations

U.S. EPA guidance requires that the concentration of contaminants in a given medium (groundwater, soil, etc.) used to represent the exposure point concentration be derived by calculating the 95% upper confidence limit on the mean (data assumed to be either normally or log-normally distributed) of sample concentrations (95% UCL) (exceptions for groundwater exist - see discussion below in Section 7.1.3.7.1). If the 95% UCL value exceeds the maximum value identified, the maximum value is to be used instead. In the present assessment, a log-normal distribution was assumed, and confirmed through analysis of covariance (Appendix U contains details for determination of exposure point concentrations). Ninety-five percent UCL values (based on a log-normal distribution) were calculated for all contaminants identified in Site media. In most instances, the 95% UCL values were greater than the maximum concentrations identified for these chemicals because of the large degree of variability within the contaminant concentration data. Therefore, maximum contaminant concentrations were used to represent most exposure concentrations for these data. UCL values were used only when less than the maximum concentration. Calculations of UCLs and comparisons to maximum concentrations is presented in Appendix U. Exposure point concentrations (either UCL or maximum concentrations) selected for each area are contained in Table 7-16.

7.1.3.7.1 Groundwater

For groundwater, there are no data available to directly describe concentrations at exposure points (private wells located off-Site). However, contamination has been detected at monitoring wells located at the periphery of the Site. Contaminants could potentially migrate off-Site in the upper aquifer and, because receptors surround the Site, there is the potential for contamination of private wells screened in the upper aquifer. Because the potential exists for migration off-Site under current land use, the U.S. EPA Region V requires evaluation of off-Site exposure to groundwater.

Monitoring well analytical data were used directly to estimate potential exposures from either the upper or lower aquifers using either the UCL or maximum contaminant concentration, as appropriate. Under current land use conditions, the exposures that may occur are off-Site. Therefore, using the UCL or maximum (lower of the two) concentration was considered to be reasonable to quantitate exposure (based on a teleconference with U.S. EPA). However, for future land use, a hypothetical well is assumed to be placed on-Site, and the maximum concentration was used. This is in accordance with recent U.S. EPA guidance (March 1991). In addition, to calculate future land use exposures, concentrations of contaminants in both aquifers were assumed to remain steady-state.

7.1.3.7.1.1 Griffith Municipal Landfill Groundwater Modeling Results

It has been shown that de-watering at the Griffith Municipal Landfill has so far limited the migration of contaminants away from the Site boundaries. However, it cannot be assumed that the landfill de-watering system will be operated indefinitely. Therefore, the U.S.G.S. Modflow model was used to evaluate the potential changes which would occur in the upper aquifer groundwater flow regime if the landfill de-watering were discontinued.

Appendix Y contains the numerical modeling results which show that in the current groundwater flow regime, the groundwater flowing beneath the landfill discharges to the de-watering excavations. In a future scenario in which the de-watering is discontinued, the creek would resume its function and groundwater would continue to discharge toward the creek west of the landfill.

The solute transport modeling which was conducted (Appendix Y) shows that the benzene level (and other landfill constituents) will migrate slowly towards the west. The upper aquifer surrounding the landfill will not be affected by leaking leachate. Upper aquifer contamination from the landfill will be limited to the aquifer area beneath the landfilled area.

A second model, a hand-calculated mass balance method was used to evaluate the potential impacts from the landfill to the upper and lower aquifer. The model used Darcy's equation to evaluate the groundwater flow rates (and discharge volumes)

within the upper and lower aquifer. The following form of Darcy's equation was used:

$$Q = -K i A$$

where:

- Q = water volume
- K = hydraulic conductivity
- i = hydraulic gradient (ft/ft)
- A = area water flows through (ft²)

The mass balance calculation to estimate potential contaminant loading can be made for each groundwater flow component using the following equation:

$$Q_a \times \text{Conc}_a = Q_b \times \text{Conc}_b$$

where:

Q = groundwater discharge (flow volume) in a quantifiable groundwater flow zone.

Conc = contaminant concentration in the quantifiable groundwater flow zone.

Four groundwater flow components can be defined as potentially affected by the landfill leachate:

- Q₁ Areal recharge across the landfill area, through the existing cover.
- Q₂ Horizontal groundwater flow in the upper aquifer beneath the landfill.
- Q₃ Vertical groundwater flow through the clay confining layer between the upper and lower aquifers.
- Q₄ Horizontal groundwater flow in the lower aquifer.

Since the concentration and discharge are known in the source area (1), a concentration can be calculated for the next and subsequent flow areas (2, 3, and 4), on the basis of the known discharges. The calculation is made with above equation 2, solved for "Conc₂"

$$\text{Conc}_2 = (Q_1 \times \text{Conc}_1) / Q_2$$

The landfill area of concern (on Figure 4-21) is approximately 1000 feet by 1000 feet, between the 634 contour lines in the northwest and southeast, and the 635 contour line in the northeast. In the current groundwater flow regime, groundwater flow is toward the landfill de-watering area, shown by the closed 625 foot contour line. Landfill contaminants were not detected in monitoring wells MW-1 and MW-15, indicating that the groundwater discharge is toward the northwest. The numerical modeling of the Site with the U.S.G.S. Modflow model (Appendix Y) showed that groundwater flow in the upper aquifer would still be toward the west, toward the creek, even if the de-watering activities are ceased at the Site.

By using known VOC concentrations, calculated flow rates, and mass balance, the potential VOC concentrations can be estimated. Assuming that the existing cover is not changed, it was calculated (Appendix Y-2) that approximately 1 million cubic feet of leachate are generated each year (Q_1); this volume represents the groundwater in the upper aquifer in the area of concern. Several VOCs were indicated in the leachate sampling results. The contaminant of concern was benzene. It was detected at concentrations between 2 and 6 ug/L, with an average concentration of 4.5 ug/L (Appendices Q-1 and R-1 list leachate results).

Potential Upper Aquifer Effects

In the present condition, the 1 million cubic feet of groundwater is collected each year by the Griffith Municipal Landfill and is not released to the environment. If the de-watering were to cease, the 1 million gallons of groundwater would discharge to the creek at the western boundary of the Site (Q_2). Under this condition, groundwater flow is symmetrical toward the creek, so the 1 million cubic feet of discharge (Q_2) to the east side of the creek would represent 50 percent of the discharge to the creek along the landfill stretch. Another 1 million cubic yards would be discharging into the creek from the west side. The mass balance calculation indicates that contaminant loading of the stream in the vicinity of the landfill would be 2.5 ug/L (benzene). This does take into account the further dilution which might occur from the creek water flowing into the landfill stretch of the stream from upstream.

Potential Lower Aquifer Effects

On the basis of laboratory results, the mean hydraulic conductivity of the clay confining layer was 4.8×10^{-8} cm/sec (Table 4-7). Field observations indicated that the downward hydraulic gradient across the confining layer is approximately 1 ft/ft (Table 4-6). With these data, it is possible to calculate the groundwater flux (Q_3) across the 1000 by 1000 foot landfill area is approximately 50,000 cubic feet per year, with an average, unattenuated concentration of 4.5 ug/L of benzene.

The groundwater flow across the confining layer (Q_3) mixes with the groundwater flowing north in the lower aquifer (Figure 4-22). Although the lower aquifer is greater than 50 feet thick, it is assumed that the groundwater leaking into the lower aquifer will diffuse across only the upper 20 feet of the aquifer. The annual volume of groundwater flow represented by the upper 20 feet of the lower aquifer can be calculated from the hydraulic conductivity estimated for the lower aquifer (Section 4.5.3.3), the horizontal gradient in the lower aquifer (Section 4.5.3.4), and the cross-sectional area of the aquifer area of concern (20 x 1000 feet). The calculation indicates that 290,000 cubic feet (Q_4) of groundwater flows to the north beneath the landfill in the upper 20 feet of the lower aquifer. Using the mass balance equation, it can be estimated that if the benzene were not attenuated during migration across the 10 foot clay confining layer, the potential benzene concentration in the lower aquifer ($Conc_4$) would be less than 1.0 ug/L (0.78 ug/L).

The relevant calculations are shown in Appendix Y-2.

7.1.3.7.2 Soils, Surface Water, and Sediment

Either the UCL or maximum chemical concentration detected was used to calculate exposure to soil, surface water, and sediment. Similar to groundwater, future exposures were based on steady-state conditions.

7.1.3.7.3 Air

VOC releases to air emanating from subsurface contamination was modeled for this risk assessment. A baseline emission estimate was generated based on either the UCL or maximum concentration, as appropriate. A dispersion model was then applied to

obtain a downwind exposure point concentration. The models used were those contained in the Superfund Exposure Assessment Manual (U.S. EPA, 1988). Refer to Appendix V for complete details on the application of these models to arrive at exposure point estimates for VOCs released to air.

A fugitive dust model was also employed to address the potential for dust release from surface contamination at Kapica-Pazmey. The methods of Cowherd, et.al. (1985) were used to arrive at fugitive dust emission rates and exposure point estimates. A description of this method and its application at the Site is contained in Appendix W.

Again, without the use of sophisticated predictive models, chemical concentrations used were assumed to remain at steady-state conditions for future land use exposure calculations.

7.1.4 Toxicity Assessment

This section addresses the nature of the toxic effects which may result from exposure to the chemicals of concern. The risk assessment addresses two general types of toxicities which may result from chemical exposure; cancer and non-cancer effects. Because these two broad types of toxicity are assumed to be expressed through different biological mechanisms, the methods used to quantify these effects are different. Although the chemicals have been divided into carcinogens or noncarcinogens, some chemicals have been evaluated as having the potential to cause both carcinogenic and noncarcinogenic effects.

7.1.4.1 Dose-Response Relationship

The type, severity, and frequency of occurrence of a given toxic effect observed within a population (response) is a function of the magnitude of chemical exposure (dose). Different chemicals which produce similar toxicities within a species usually do so at different concentrations (i.e., have different toxic potencies). These relative differences in the dose-response relationships among chemicals are addressed in the risk assessment by considering "critical toxicity values" developed by the U.S. EPA. Critical toxicity values have been derived for potential noncarcinogenic effects and potential carcinogenic effects of the chemicals and are termed reference doses (RFD) and slope factors (SF), respectively.

Two sources of critical toxicity values were used. The primary source was the U.S. EPA's Integrated Risk Information System (IRIS) database. A secondary source of data was the Health Effects Assessment Summary Table (HEAST) published quarterly by the U.S. EPA. Critical toxicity values were not available for many of the chemicals of potential concern. To establish those toxicity values, the Environmental Criteria and Assessment Office (ECAO) and the U.S. EPA Region V Technical Support Group were contacted to provide additional values and guidance, as appropriate.

7.1.4.1.1 Noncarcinogenic Effects

Noncarcinogenic effects of chemicals are assumed to display a threshold phenomenon, i.e., effects are not observed below a given chemical concentration (threshold dose). Therefore, a health risk is thought to exist only if established threshold doses are exceeded.

Noncarcinogenic health effects include a variety of toxic effects on body systems such as renal toxicity (toxicity to the kidney), teratogenicity (damage to the developing fetus), and central nervous system disorders. In many cases, organisms have adaptive mechanisms that must be overcome before a toxic endpoint (effect) is manifested. The toxicity of a chemical is assessed through a review of toxic effects noted in short-term (acute) animal studies, long-term (chronic) animal studies, and epidemiological investigations.

The noncarcinogenic dose-response relationship is addressed in the toxicity assessment by considering RFDs, expressed in mg contaminant/kg body weight-day, which are levels of contaminants not expected to cause adverse health effects in humans, including sensitive subsets of the population. RFDs are generally estimated from No-Observed-Adverse-Effect-Levels (NOAEL), determined from animal studies, which are the highest chemical concentrations which produce no adverse effects. Safety factors related to various assumptions made (e.g., animal to human extrapolation) are incorporated in the derivation of the values to result in a more health-protective estimation.

RFDs for some inorganic compounds are for specific forms (e.g., hexavalent and trivalent chromium). The chemical analyses performed do not, however, report concentrations of specific forms, but rather give results in terms of "total" inorganic chemical. In such situations, it was assumed that unless otherwise known, the most toxic form is present and its RFD used.

7.1.4.1.2 Carcinogenic Effects

Presently in the risk assessment process, all carcinogens are considered to have a dose-response relationship with no threshold. Thus, theoretically, any exposure is associated with some degree of risk.

The cancer potentials of carcinogens are known with varying degrees of certainty, depending on the amount and quality of scientific information available. The U.S. EPA has developed a system to review this information and to classify chemicals as to their likelihood of causing cancer. For example, this classification scheme distinguishes between chemicals which are known human carcinogens (Group A) and chemicals which are probable human carcinogens (Group B), based on their cancer causing

properties in animal studies. The dose-response relationship for an established or potential carcinogen is incorporated into the SF; a value expressed in $(\text{mg/kg-d})^{-1}$, which is directly proportional to the cancer potency of the chemical.

7.1.4.2 Critical Toxicity Values and Toxicity Profiles

The critical toxicity values (RFDs and SFs) used in the present risk assessment are shown in Table 7-17. Toxicity values are generally based on the level of a chemical "administered" to a test animal. This situation does not account for the ability of the animal to absorb the compound into the blood stream. Toxicity values can be adjusted to account for this factor by incorporating an estimate of the level of absorption which is likely to occur. In the present risk assessment it was necessary to adjust toxicity values based on "administered" doses to an "absorbed" dose basis because contaminant dose estimates calculated for the dermal route of exposure provide an "absorbed" dose estimate. Thus, all contaminant dose estimates for all dermal exposure routes were compared to adjusted toxicity values to estimate health risk. Absorption estimates and critical toxicity values were approved by the Environmental Criteria and Assessment Office.

Toxicity values are based on a "critical" toxic effect in an animal. These are generally the most sensitive effects observed (those detected at lowest doses). The critical effects for the chemicals of potential concern are listed in Table 7-18. In addition, the uncertainty factor used to develop the reference dose and the U.S. EPA carcinogen classification for potential carcinogens are also summarized.

7.1.5 Risk Characterization

In this section, estimates of contaminant exposure are compared with toxicity information to arrive at an estimate of potential human health risk. Two general types of toxicity endpoints are evaluated for chemicals of potential concern in this assessment, i.e., cancer and non-cancer effects. Because the assumptions related to how chemicals produce cancer effects and non-cancer toxicities differ, the methods employed to qualify these risks also differ. These are described below.

7.1.5.1 Procedures Used to Quantify Health Risk

7.1.5.1.1 Non-Cancer Effects

Estimating the risk of a non-cancer health effect was accomplished by calculating a hazard quotient. The hazard quotient for a chemical is calculated by dividing the estimated contaminant dose by the Reference Dose for the chemical as shown below:

$$\text{Hazard Quotient} = \frac{\text{Contaminant Dose Estimate (mg/kg-d)}}{\text{Reference Dose (mg/kg-d)}}$$

For a given exposure pathway, the hazard quotients for all chemicals of potential concern are added to arrive at a total. This value is referred to as the hazard index (HI) for the exposure pathway. If the HI (or hazard quotient) exceeds unity (1), there may be a potential health risk associated with exposure via the particular pathway (or chemical) evaluated.

7.1.5.1.2 Carcinogenic Effects

The cancer risk value is an estimate of an individual's lifetime likelihood of developing cancer over and above the existing background chance of developing cancer. A cancer risk of 1×10^{-6} , for example, may be interpreted as an increased risk of one in one million of developing cancer over a person's lifetime. This risk may also be interpreted on a population basis, to predict that one additional case of cancer may occur in a population of one million people.

Generally, when the HQs for several contaminants give an additive HI > 1.0, the HQs are regrouped according to target organ effect or mechanism of action. If the HI for all chemicals having the same target organ effect is > 1.0, there is a likelihood of the effect. However, in this risk assessment, there are some chemicals which tended to exceed an HQ of 1.0. Because these chemicals dominate the HI, regrouping by target organ effect was not considered necessary.

The cancer risk is estimated by multiplying the estimated contaminant dose by the slope factor for the chemical as shown below:

$$\text{Cancer Risk} = \text{Estimated Contaminant Dose (mg/kg-d)} \times \text{Slope Factor (kg-d/mg)}$$

The cancer risks associated with specific chemicals within an exposure pathway are assumed to be additive. Therefore, cancer risks for individual chemicals are summed to arrive at a total exposure pathway cancer risk.

7.1.5.2 Qualitative Health Risk Assessment

In addition to the quantitative risk estimates, a qualitative risk assessment was conducted for lead. Lead is known to be a potent human neurotoxin at very low exposure levels. There are currently no U.S. EPA approved toxicity values for lead. Rather, in the interim, until an appropriate toxicity value can be developed for this metal, the U.S. EPA has been utilizing a new pharmacokinetic model (i.e., Lead Uptake/Biokinetic) or interim soil cleanup guidelines of 500-1,000 mg/kg soil (OSWER Directive 99355.4-02). Lead exists on-Site at concentrations of 17,000 mg/kg in soils. At this concentration, for purposes of this assessment, the "Interim Guidance in Establishing Soil Lead Clean-up Levels at Superfund Sites" was used.

The existing CERCLA standard for lead in soil is based on the 1985 recommendation of the Centers for Disease Control (CDC). The U.S. EPA OSWER Directive discusses appropriate lead levels:

"This guidance adopts the recommendation contained in the 1985 Centers for Disease Control (CDC) statement on childhood lead poisoning and is to be followed when the current or predicted land use is residential. The CDC recommendation states that ...lead in soil and dust appears to be responsible for

blood levels in children increasing above background levels when the concentration in the soil or dust exceeds 500 to 1000 ppm. Site-specific conditions may warrant the use of soil cleanup levels below the 500 ppm level or somewhat above the 1000 ppm level.”

Based on this recommendation, for purposes of this assessment, a soil-lead concentration exceeding 500 mg/kg was compared to the soil-lead concentrations on-Site.

7.1.5.3 Superfund EPA Health Risk Goals

The U.S. EPA has developed program goals for potential health risks estimated from exposure to contaminants at Superfund sites. For chemicals which may cause non-cancer health effects, acceptable exposure levels are intended to represent concentration levels to which the human population, including sensitive subgroups, may be exposed without adverse effect during a lifetime or part of a lifetime, incorporating an adequate margin of safety (i.e., a HI of less than 1). For known or suspected carcinogens, the 1×10^{-6} risk level is used by U.S. EPA as a “point of departure” for determining remediation goals. Cancer risks which are between 1×10^{-6} and 1×10^{-4} may or may not be acceptable depending on other risk management factors (e.g., ARARs, nature of exposure, efficacy of treatment technologies, cost, and others) applicable to the Site.

7.1.5.4 Public Health Evaluation

Potential health risks were evaluated for contaminant exposures based on two land-use scenarios; current Site conditions and possible future Site conditions. As part of these evaluations, risks to groundwater (upper and lower aquifers), surface and subsurface soils, surface water and sediment, and air (via fugitive dust and volatiles emissions) were assessed. In addition, the Site was segregated into “areas” (on-Site containment, off-Site containment, still bottoms and treatment lagoon, and Kapica-Pazmey areas) to assess location-specific contamination. Potential risks to groundwater downgradient of the Griffith Municipal Landfill were also evaluated. The risks, based on the assumptions and conditions provided in this assessment, are discussed below. Tables 7-19 through 7-37 summarize risks only for chemicals which may contribute substantially to the total exposure pathway risk. Thus, these tables summarize chemicals associated with cancer risk greater than 1×10^{-6} and chemicals associated with hazard quotients greater than 0.01. Table 7-38 contains population-based risk totals including a multi-

population assessment for the maximally exposed individual. For a detailed summary of risk values associated with all chemicals of potential concern, the reader is referred to Appendix X.

7.1.5.4.1 Summary of Potential Health Risks Based on Current Land Use

Current land use health risks associated with exposure to contaminated Site media were evaluated for off-Site residents, trespassers (children who may occasionally play on-Site), and on-Site workers at the Site. The likelihood of exposure to populations from any of the pathways in this risk assessment is considered to be low and generally results in risk estimates that are conservative.

As has been referred to previously in this risk assessment, risks are based on hypothetical exposure scenarios. The risks quantified are approximations of potential health hazards that should be viewed on a relative risk basis, rather than on actual risk basis.

The risks calculated for groundwater were based on samples that were filtered for metals but not filtered for organics. The unfiltered samples generally result in sediments (suspended solids) being collected. This point deserves emphasis in that, the presence of certain organic chemicals (i.e., those with strong binding affinity to soils; high K_{oc}) in groundwater samples is likely the result of the incorporation of sediments into the sample (i.e., the chemical is adsorbed to sediments and not actually in solution). PCBs for instance, bind (adsorb) strongly to soils and likely have been introduced into the groundwater sample as a suspended sediment. It is also important to note that arsenic, while contributing to groundwater risks, has a maximum detected concentration on-Site of 43.2 ug/L (Table 7-2) which is lower than the Maximum Contaminant Level (MCL) Standard of 50 ug/L. The MCL value for arsenic assumes that drinking water is the only route of exposure to arsenic, and arsenic is the only chemical of concern.

In this section, health risks have been discussed separately for individual populations/subpopulations, and combinations of the same to evaluate the maximally exposed individual.

7.1.5.4.1.1 Potential Health Risks to Off-Site Residents

Off-Site residents were considered to be exposed to contaminants released to groundwater and air under current land use conditions. Exposure to groundwater was considered plausible from both the upper and lower aquifers. Exposure to contaminants in air (fugitive dusts and volatiles emissions) was considered in the risk estimate for off-Site residents. Total pathway/population risks (cancer and non-cancer) are summarized in Table 7-38 while Tables 7-19 through 7-22 contain chemical, route-specific, and total pathway risks for the off-Site populations in consideration of the current land use exposure assumptions.

Potential risk to children (i.e., exposure to contaminated water from the upper aquifers while playing) from non-cancer health effects were above a level of concern as indicated by an exposure pathway HI greater than unity (1). This potential health threat is primarily the result of dermal exposure to 4-methyl-2-pentanone (54% of the risk). Several other chemicals of potential concern exceeded a hazard quotient of 1, including acetone, 1,2-dichloroethene, 2-butanone, ethylbenzene, dimethyl ethylbenzene, branched alkanes, and non-cyclic acids. 4-methyl-2-pentanone and acetone combine for a HI which is greater than 80% of the non-cancer hazard. The primary toxicity associated with these chemicals is liver and kidney effects (see Table 7-18).

The total cancer risk to children exposed to contaminated groundwater (upper aquifer only) was calculated to be 1.7×10^{-2} . This exceeds the U.S. EPA 1×10^{-6} point of departure. Dermal absorption of benzene is the primary route and chemical associated with this risk although chloromethane, vinyl chloride, methylene chloride, trichloroethene, tetrachloroethene, bis(2-chloroethyl)ether, PCB, and arsenic were also determined to exceed the 1×10^{-6} point of departure (see Table 7-22). Cyclic ketones (tentatively identified compounds) were considered similar in chemical structure to isophorone, and the slope factor for isophorone was used to quantitate a cancer risk value for this TIC group which exceeded 1×10^{-6} . There is substantial uncertainty in this result since there is no verified slope factor or reference dose for this TIC group. Isophorone was used as an approximation/representation for this TIC group (see Section 7.1.2.2 and Table 7-12).

The total pathway HI value for off-Site residents exposed to contaminants in air and groundwater is 2.1. This value takes into consideration ingestion, dermal absorption, and inhalation (VOCs released from groundwater during household use) of groundwater from the lower aquifer, and inhalation of fugitive dusts and VOCs in ambient air (Table 7-38). None of these exposure pathways, when viewed independent of one another, has a HI greater than 1 nor does any specific chemical have a HQ greater than 1.

The HI of 2.1 does not take into consideration each chemical's toxic endpoint. Arsenic, barium, manganese, cyclic alcohols (as represented by benzyl alcohol), and oxygenated alcohols (as represented by ethylene glycol monobutyl ether) contribute to the cumulative HI of 2.1; this assumes each of these chemicals has the same toxic endpoint. However, each of these chemicals actually have toxicities that differ (e.g., arsenic is associated with keratosis and hyperpigmentation via chronic-oral exposure; chronic oral barium exposure results in high blood pressure, and so on, see Table 7-18). The individual HQs for each chemical is less than unity (1), and because each chemical of concern has a different toxic endpoint, a cumulative HI greater than 1 cannot be calculated. Therefore, there does not appear to be a noncancer concern for the off-Site adult residential population when evaluating on the basis of toxicity.

The total cancer risk for off-Site adult residents is 4.5×10^{-4} (Table 7-38). Ingestion of arsenic and bis(2-chloroethyl)ether in groundwater from the lower aquifer contributes a substantial portion of this risk. Inhalation of several volatile compounds (methylene chloride, 1,1-dichloroethene, chloroform, carbon tetrachloride, trichloroethene, and benzene) from ambient air combine for a total cancer risk of 1.6×10^{-4} . Cancer risk estimates for fugitive dust inhalation did not exceed levels of concern.

7.1.5.4.1.2 Summary of Potential Health Risks to Trespassers

Trespassers (children-adolescents gaining unauthorized entrance to the Site) were assumed to be exposed to contaminants in several media including surface soils at Kapica-Pazmey, surface water and sediment in the wetlands and drainage ditches, and fugitive dusts and volatiles in ambient air. Table 7-38 provides a summary of hazard indices and cancer risks for this population. This table indicates that the total hazard

indices for all pathways is greater than 1 (1.9×10^{-1}) with most of the concern attributed to ingestion and dermal absorption of surface soils at Kapica-Pazmey. Total cancer risks for all pathways assumed to occur for trespassers is 6.3×10^{-3} . This multiple pathway assessment indicates a cancer risk exceeding the 1.0×10^{-6} point of departure.

In assessing non-cancer risks for the trespasser scenario, none of the chemical-specific HQs for inhalation of fugitive dusts nor the HI for the total pathway exceeded or even approached unity (1) (Table 7-27). Therefore, inhalation of fugitive dusts is not considered to pose a health hazard to trespassers at the Site. Inhalation of volatiles in ambient air by Site trespassers had an inhalation HI of 5.3 (Table 7-26). Non-cyclic acids (TIC group represented by acrylic acid; Table 7-12), and chloroethane, both have HQs greater than 1, and together make up approximately 83% of the HI (5.3). The remaining chemicals have individual HQs less than 1 (Table 7-26).

No individual chemical in surface water or sediment had a chemical-specific HQ greater than 1 (see Tables 7-24 and 7-25). A hazard index of 1.0 was exceeded when adding chemical-specific HQs (this assumes the additive effects of these chemicals affect the same target organ) for the surface water pathway. However, there is no cumulative HI greater than unity when combining chemicals on the basis of similar toxic endpoints.

The non-cancer risk to trespassers exposed to surface soils at Kapica-Pazmey was estimated to be 1.3×10^{-1} (Table 7-23). The majority of the hazard index was not associated with a specific chemical. Rather, exposure to a number of contaminants (i.e., antimony (16%; HQ = 2.1), bis(2-ethylhexyl)phthalate (12%; HQ = 1.6), toluene (11.1%; HQ = 1.4), cadmium (10%; HQ = 1.3), ethylbenzene (10%; HQ = 1.3) and tetrachloroethene (9%; HQ = 1.2)) contributed nearly equal proportions of risk to the hazard index. These contaminants illicit varying types of toxic effects (refer to Table 7-18).

As mentioned previously in Section 7.1.5.2, a quantitative health assessment for lead could not be made due to a lack of toxicity values approved by the U.S. EPA. Rather, an interim soil-lead clean-up criteria of 500 mg/kg established by the U.S. EPA for Superfund sites was used as a qualitative indicator of the health risk associated with lead exposure.

Surface soils at Kapica-Pazmey exceed the 500-1,000 mg/kg interim lead criteria. Surface soil lead concentrations ranged from 401 mg/kg to 16,200 mg/kg. The average (arithmetic) concentration was calculated to be 8,300 mg/kg. Lead exposure has been shown to cause damage to the central nervous system which leads to learning impairment in young children.

The cancer risk due to trespasser exposure to surface water is 1.6×10^{-4} (Table 7-24). Seventy-three percent of this risk is due to dermal contact with PCBs. The surface water results likely indicate the presence of sediments in the surface water samples as PCBs absorb preferentially to solids, particularly those sediments with high organic content. PCBs are less likely to be in solution, based on this tendency and their low water solubility. For exposure to sediments, the cancer risk estimate for trespassers is 2.2×10^{-4} (Table 7-25). Seventy percent of the sediment cancer risk is due to dermal contact and incidental ingestion of carcinogenic PAHs (1.5×10^{-4}) and 28% is attributed to dermal absorption and incidental ingestion of PCBs (6.0×10^{-5}).

There is no cancer risk greater than U.S. EPA's point of departure associated with exposure of trespassers to fugitive dusts (Table 7-27). Inhalation of volatiles by trespassers on-Site results in a cancer risk estimate of 2.9×10^{-4} (Table 7-26). Greater than 90% of this risk is associated with inhalation of 1,1-dichloroethene (highest exposure point concentration located at the off-Site containment area), chloroform (highest exposure point concentration located at the off-Site containment area), and carbon tetrachloride (highest exposure point concentration located at the still bottoms/treatment lagoon area).

The cancer risk estimate for exposures to Kapica-Pazmey surface soils is 5.7×10^{-3} (Table 7-23). Approximately 85% of this total is attributed to PCB exposures (4.8×10^{-3}), primarily via dermal absorption (4.7×10^{-3}). PAHs account for approximately 13% of the total cancer risk (6.8×10^{-4}).

7.1.5.4.1.3 Summary of Potential Health Risks to On-Site Workers at the Site

Site workers were assumed to be exposed via inhalation to contaminated fugitive dusts generated at the Kapica-Pazmey location and to volatiles released from subsurface (buried) waste from various areas located around the Site. The summary of hazard indices and cancer risks for these pathways is contained in Table 7-38. The HI estimated for the Site worker is 9.9, which exceeds unity assuming the same toxic endpoint for the chemicals contributing to the HI. The cancer risk estimated for this population is 1.6×10^{-3} (the cancer risk, like the non-cancer risk, is primarily associated with exposure to volatiles emissions and not fugitive dusts).

The fugitive dust HI for this population is substantially less than 1 and does not pose a non-cancer health hazard (Table 7-29). The risk to Site workers is primarily from exposure pathways evaluated for volatiles emissions emanating from buried wastes. In assessing which chemicals are contributing to the non-cancer risk for inhalation of volatiles emissions, non-cyclic acids (TIC group), and chloroethane have chemical-specific hazard quotients that exceeds 1 (Table 7-28). Thus, based on the assumptions used to evaluate Site worker exposure to chemicals volatilizing in ambient air, there may be a noncancer hazard associated with exposure to VOCs in ambient air, and in particular, chloroethane, and noncyclic acids.

The cancer risk estimated for fugitive dust exposure is much less than the U.S. EPA's point of departure (Table 7-29). The cancer risk estimate for inhalation of VOCs in ambient air is 1.6×10^{-3} (Table 7-28). The majority of this risk is associated with 1,1-dichloroethene (highest exposure point concentration used to model VOC emissions is from the off-Site containment area), chloroform (highest exposure point concentration found at the off-Site containment area), and carbon tetrachloride (highest exposure point concentration located at the still bottoms/treatment lagoon area).

7.1.5.4.1.4 Potential Maximally Exposed Individuals

An off-Site resident was considered to have potential exposure over a 30-year period. Exposure to this individual (off-Site resident) may be the result of several, cumulative exposures depending on their individual behavior. For instance, during the 30-year exposure period, continuous exposure via drinking water from the lower aquifer was

assumed (i.e., ingestion, dermal absorption, and inhalation of VOCs while showering). In addition, this individual may also be exposed as a child, age 5 to 15, to contaminated water from the upper aquifer while swimming in a pool. Thus, this behavioral-based exposure is additive. The individual may be exposed while trespassing (age 5 to 15) on-Site which would also be additive.

The subpopulation RMEs are distinctive, in that different contaminant sources and behaviors (exposures) were assumed. The RMEs have been added, where appropriate, to evaluate the maximally exposed individual. Table 7-38 identifies the populations, based on behaviors, that could be considered to result in the maximally exposed individual.

In one instance, the maximally exposed individual was considered to be an off-Site resident with exposure as a child to upper aquifer contamination while playing (i.e., swimming in a pool). This combination results in a non-cancer health risk of 1.6×10^{-2} . Dermal exposure to 4-methyl-2-pentanone while swimming is the predominant route of exposure and chemical of concern. The cancer risk of 1.7×10^{-2} is also due to swimming as a child in upper aquifer groundwater. Benzene and vinyl chloride make up the majority of this risk estimate.

In a separate example, the maximally exposed individual was thought to have exposure as an off-Site resident and trespasser. The non-cancer hazard index calculated for this individual is 2.1×10^{-1} . The primary pathways and chemicals that would result in this non-cancer hazard index are associated with exposures while trespassing on-Site. Similarly, the cancer risk calculated (6.7×10^{-3}) for an off-Site resident who has additional exposure as a trespasser, is predominantly due to trespasser exposures. See Section 7.1.5.4.1.2 for further discussion on trespasser health concerns.

Another illustration of the maximally exposed individual combines the off-Site resident with childhood exposure while swimming in a pool, and while trespassing (playing) on-Site. The non-cancer hazard index is 1.7×10^{-2} resulting primarily from exposure to upper aquifer groundwater while swimming (see Section 7.1.5.4.1.1). Nearly 71% of

the total cancer risks for this individual (2.4×10^{-2}) is also the result of exposure as a child while swimming in a pool containing contaminated groundwater from the upper aquifer (see Section 7.1.5.4.1.1).

Finally, the maximally exposed individual was considered to possibly be exposed as an off-Site resident who also works at the Site. A hazard index of 1.2×10^{-1} and cancer risk of 2.1×10^{-3} were estimated for this individual. Inhalation of VOCs as a Site worker was the primary route of exposure associated with both the HI and cancer risks (see Section 7.1.5.4.1.1 for discussion of chemicals contributing to these estimates).

7.1.5.4.2 Summary of Potential Health Risks Based on Future Land Use

Future land use health risks associated with exposure to contaminated Site media were evaluated for residents living on-Site. The future land use scenario assumed hypothetically, that a residential development may be plausible at the Site. This coincides with recent guidance and is required by the U.S. EPA RPM and U.S. EPA Technical Support Group. The likelihood of this type of occurrence is unknown but, is considered to be quite low.

7.1.5.4.2.1 Potential Health Risks to Hypothetical Residents Living On-Site

To address potential health risks due to contamination associated with operable areas of the Site (e.g., on-Site containment area, Kapica-Pazmey area, off-Site containment area, and the still bottoms/treatment lagoon area), a resident was assumed to exist at each of these locations, and be exposed to the contaminated soils at each location independent from the other areas. For example, a resident is assumed to have their home on the on-Site containment area and is exposed to the soils at this location only. Risks associated with other media (for exposures to contaminants in surface water and sediments, groundwater, and air) for a resident residing at the on-Site containment location are the same as that for a resident assumed to have their home at the other areas. Therefore, the only difference in risks at the Site is associated with exposure to soils from each area. This approach was taken to assess the soils on a localized basis rather than on a Site-wide basis and to facilitate analysis in the Feasibility Study.

Total pathway risks (non-cancer and cancer) are summarized in Table 7-38 for each of the populations residing at the different areas. Tables 7-24, 7-25, and 7-30 through 7-37 contain chemical-specific, route-specific, and total pathway risks for the hypothetical residents.

Exposure to groundwater was assumed to occur from both the upper and lower aquifers, nonconcurrently (i.e., residents had a well in either the lower or upper aquifer - not both at the same time). For purposes of this discussion, only the upper aquifer is addressed because the risks associated with exposure to it were greater than that of the lower aquifer.

The non-cancer health risk for a hypothetical resident (regardless of location on-Site) exposed to contaminated groundwater in the upper aquifer was estimated to be 3.3×10^{-2} (Table 7-31). This assumes that each chemical of concern has the same toxic effect.

Approximately 47% of the HI is due to exposure to 2-butanone (HQ of 1.6×10^{-2}); 23% to 4-methyl-2-pentanone (HQ of 7.6×10^{-1}), and 14% to non-cyclic acids (HQ of 4.6×10^{-1} ; TIC group represented by acrylic acid). 2-Butanone toxicity via inhalation is manifested by central nervous system effects, and fetotoxic effects based on oral studies on rats (Table 7-18).

Exposure to surface water and sediments for on-Site residents was assumed to be similar to that of Site trespassers under the current land use scenario that is, on an occasional basis. The total surface water HI was calculated to be 1.3 (Table 7-24), which assumes similar toxic endpoints for the chemicals of concern contributing to the HI. A HI of 1 is not exceeded when evaluating chemicals based on each chemicals toxic endpoint; therefore, there does not appear to be a non-cancer health concern related to surface water exposure. The HI for sediments is less than unity even when assuming conservatively that the chemicals of concern have the same toxic effect, and thus, exposure to sediments is not considered to pose a non-cancer health hazard to future on-Site residents.

The non-cancer HI value for inhalation of VOCs in air is 1.6×10^{-1} . The majority of this HI value is associated with non-cyclic acids (47%). Non-cyclic acids (HQ of 7.7) and chloroethane (HQ of 5.9) comprise approximately 83% of this HI value. These are the only chemicals of potential concern associated with inhalation of VOCs in ambient air with HQs greater than 1.

The non-cancer HI values for potential on-Site residents associated with subsurface soils from each of the areas is summarized below and in Tables 7-33 through 7-37.

- On-Site Containment Area

- The total pathway HI value for exposures to subsurface soils assumed to be unearthed for residential development and brought to the surface is 5.0×10^{-1} (Table 7-33) based on similar toxicities. Several chemicals exceed unity by themselves (i.e., $HQ > 1$), and tend to drive the HI result (see Table 7-18 for toxic endpoints for chemicals of concern).
- 47% of this value is associated with tetrachloroethene, 32% with toluene, and 11% with ethylbenzene. Only two other chemicals of potential concern had HQ values greater than 1; naphthalene and bis(2-ethylhexyl)phthalate (Table 7-33).

- Still Bottoms/Treatment Lagoon Area

- The total pathway HI for exposure to subsurface soils at the still bottoms/treatment lagoon area was estimated to be 4.1×10^{-2} (Table 7-34). Because this value exceeds unity, it may be interpreted to mean that there is a potential non-cancer health concern associated with subsurface soil exposure in this area. This is because some chemicals have HQ values that exceed unity.
- 58% of this value is associated with carbon tetrachloride (HQ of 2.4×10^{-2}), 7% with n-chain alkanes (HQ of 3.0×10^{-1}), and 10% with nitrogenated benzenes (HQ of 3.9×10^{-1}) (Table 7-34).
- Other chemicals with HQ values greater than 1 include: 1,2-dichloroethene (cis), chloroform, 1,1,1-trichloroethane, 4-methyl-2-pentanone, tetrachloroethene, toluene, ethylbenzene, isophorone, naphthalene, hexachlorobutadiene, bis(2-ethylhexyl)phthalate, endosulfan I, 4,4'DDT, antimony, cadmium, methyl propyl benzenes, dimethyl ethyl benzenes, halogenated alkanes and branched alkanes. Numerous other chemicals of potential concern approach a HQ of 1.

- Off-Site Containment Area

- Table 7-35 contains a summary of HQs for chemicals of potential concern at the off-Site containment area. A total pathway HI value (based on similar toxic endpoints) of 1.0×10^{-3} was calculated.

- The following chemicals were determined to contribute substantially to the potential hazard: tetrachloroethene - 18% (HQ of 1.8×10^{-2}), 2-butanone - 15% (HQ of 1.6×10^{-2}), nitrogenated benzenes (TIC group) - 15% (HQ of 1.6×10^{-2}), bis(2-ethylhexyl)phthalate - 11% (HQ of 1.1×10^{-2}), 4-methyl-2-pentanone - 9% (HQ of 9.6×10^{-1}), 1,1,1-trichloroethane - 7% (HQ of 6.6×10^{-1}), cadmium - 3% (HQ of 3.3×10^{-1}), and naphthalene 3% (HQ of 2.8×10^{-1}).
- Besides the chemicals above, 24 additional chemicals of potential concern had a HQ greater than 1.
- Kapica-Pazmey Area (Surface Soils - assuming no excavation for residential development)
 - The total pathway HI value for exposures to surface soils is 3.4×10^{-1} (Table 7-36). Because the HI exceeds unity there may be a potential non-cancer health risk associated with exposure to Kapica-Pazmey surface soils. Again, this is possible because several chemicals of concern, in and of themselves, have a HQ value which exceeds unity.
 - A single chemical did not overwhelmingly contribute to the cumulative HI, rather a number of compounds had HQs of 1 to 2 which together, contributed nearly equal proportions of risk. The following metals and organic compounds have HQ values that exceed 1 (Table 7-36): Metals - antimony, barium, cadmium, and chromium; Organics - tetrachloroethene, toluene, ethylbenzene, naphthalene, and bis(2-ethylhexyl)phthalate.
- Kapica-Pazmey Area (Subsurface Soils and Surface Soils-Mixed)
 - The total pathway HI value for exposures to mixed soils is 4.2×10^{-2} (Table 7-37).
 - As with Kapica-Pazmey surface soils, the majority of the pathway risk is not attributed to a single chemical. Rather, a number of chemicals had HQs of 1 to 2 which contributed to the cumulative HI (Table 7-37). Also, because several chemical-specific HQs exceeded unity, it was not necessary to regroup the chemicals based on toxic endpoints. Refer to Table 7-18 for toxic effects associated with those chemicals determined to provide the greatest potential hazard.
 - Antimony, barium, cadmium, and chromium had individual HQs greater than 1. Tetrachloroethene, toluene, ethylbenzene, naphthalene, and bis(2-ethylhexyl)phthalate also had HQ values greater than unity.

The highest total pathway, non-cancer risk for a hypothetical resident at the Site is associated with residential development at the off-Site containment area. The still bottoms/treatment lagoon area has the next highest hazard index followed by Kapica-Pazmey surface soils and Kapica-Pazmey soils (all depths), and finally the on-Site containment area. The difference in the noncancer risk between these areas is no greater than a factor of approximately 3.5.

Similar to current Site conditions, a qualitative health assessment was conducted for soil-lead exposure. In each of the areas considered (i.e., On-Site Containment, Still Bottoms/Treatment Lagoon, Off-Site Containment, and Kapica-Pazmey) soil-lead concentrations exceeded the 500 -1,000 mg/kg interior soil-lead clean-up criteria set by the U.S. EPA. Concentrations of lead on average (arithmetic) were highest at Kapica-Pazmey (8,300 mg/kg), the Off-Site Containment area (1,100 mg/kg), and Still Bottoms/Treatment Lagoon (840 mg/kg) areas. Average soil-lead concentrations in the On-Site Containment area were substantially less than the other areas (i.e., 110 mg/kg).

For purposes of this discussion, cancer risks estimated for hypothetical residents have been evaluated in the same fashion as non-cancer risks. That is, the cancer risks estimated for groundwater, surface water and sediment, and air are the same for a hypothetical resident regardless of the location on-Site. Risks estimated for exposure to soils has been evaluated on a location-specific basis.

Cancer risks estimated for exposure to groundwater are greatest in the upper aquifer. The cancer risk associated with groundwater exposure is approximately 8.7×10^{-2} . This is well in exceedance of the U.S. EPA's 1×10^{-6} point of departure. Chemicals which contribute to this risk are provided in Table 7-31. As is evident in this table, nearly 61% of the risk is associated with dermal absorption, inhalation, and ingestion of benzene in groundwater. Numerous other chemicals of potential concern exceed the 1×10^{-6} point of departure (see Table 7-31).

Cancer risk estimates for occasional exposure to surface water and sediment is contained in Tables 7-24 and 7-25. Cancer risks due to surface water exposure were estimated to be 1.6×10^{-4} . Dermal contact with PCBs (likely absorbed on sediment) accounts for approximately 73% of this risk estimate. The permeability constant for PCBs is based on PCBs not bound to sediments. Thus, this result likely over-estimates the PCB risk. Benzene, bis(2-chloroethyl)ether, and arsenic also exceed the 1×10^{-6} point of departure for surface water exposure. Sediment exposures result in a cancer risk estimate of 2.2×10^{-4} . In this instance, carcinogenic PAHs and PCBs combined, comprise nearly 100% of the risk estimate (Table 7-25).

Inhalation of VOCs in ambient air emanating from buried wastes at the Site results in a cancer risk estimate of 2.7×10^{-3} . As is evident in Table 7-32, most of this risk is associated with 1,1-dichloroethene, carbon tetrachloride, and chloroform. Other chemicals of potential concern also exceed the U.S. EPA point of departure (see Table 7-32).

The cancer risk estimates for soils at the various locations on-Site are summarized below and in Tables 7-33 through 7-37.

- On-Site Containment Area
 - The cancer risk estimated for exposure to subsurface soils at the on-Site containment area is 6.8×10^{-3} (Table 7-33).
 - 76% of this risk is due to tetrachloroethene, 15% to PCBs, and 5% to benzene. Several other chemicals of potential concern exceed the 1×10^{-6} point of departure.
- Still Bottoms/Treatment Lagoon Area
 - Cancer risk estimated for the subsurface soils in this area is 3.8×10^{-2} (Table 7-34).
 - The majority of this risk is attributable to PCBs (48%), carbon tetrachloride (24%), bis(2-chloroethyl)ether (11%), bis(2-ethylhexyl)phthalate (6%), and tetrachloroethene (4%).
 - Numerous other chemicals of potential concern exceed the U.S. EPA 1×10^{-6} point of departure.
- Off-Site Containment Area
 - Table 7-35 indicates a cancer risk estimate for exposure to subsurface soils in the off-Site containment area of 1.5×10^{-1} .
 - Chemicals of potential concern that contribute substantially to this risk include PCBs, tetrachloroethene, PAHs, bis(2-ethylhexyl)phthalate, 1,4-dichlorobenzene, 1,1-dichloroethene, and trichloroethene. There are several other chemicals of potential concern besides these that have cancer values exceeding the 1×10^{-6} point of departure (see Table 7-35).
- Kapica-Pazmey (Surface Soils - assuming no excavation for residential development)
 - A cancer risk value estimated for exposure to surface soils in the Kapica-Pazmey area is 4.5×10^{-2} (Table 7-36).

- 85% of this risk is estimated to be the result of PCB exposure from these soils. 12% is from PAH exposure. Other chemicals of potential concern in surface soils from this area resulted in cancer risks exceeding the U.S. EPA point of departure (see Table 7-36).
- Kapica-Pazmey (Subsurface Soils and Surface Soils - Mixed)
 - Exposure to subsurface soils from Kapica-Pazmey results in a cancer risk of 1.8×10^{-2} (Table 7-37).
 - PAHs and PCBs combine for 91% of the risk estimate. Several other organics and inorganics in soils at this location also exceed the 1×10^{-6} point of departure (Table 7-37).

The multiple exposure assessment indicates that cancer risk appears to be greatest for a resident residing at the off-Site containment area (2.9×10^{-1}). A factor of approximately 2.4 separates the cancer risks from the five areas evaluated.

7.1.5.5 Uncertainties in the Risk Assessment Process

The risk assessment process incorporates numerous assumptions and is therefore associated with a great deal of uncertainty. Thus, calculated risk estimates are not to be construed to necessarily represent actual risks. Proper interpretation of health risk values requires consideration of the uncertainties and assumptions involved in the risk calculations.

The risk assessment uses hypothetical scenarios and conservative assumptions to quantify potential risks for current and future land uses which do not necessarily, but could, reflect actual risks. However, assumptions used in this assessment are an attempt to characterize a reasonable hypothetical useage.

Assumptions are applied in all steps of the process including Site contaminant characterization, exposure assessment, toxicity assessment, and risk characterization. These assumptions may over- or under-estimate risks. Examples of some key uncertainty factors and assumptions applied in the risk assessment are described below, as well as indications of their biases.

- Assume Site is fully characterized. The presence of areas of contamination not identified may result in an under-estimation of Site risks.
- Assume identified chemicals are associated with the majority of Site health risks. The presence of highly toxic compounds not analyzed for or identified compounds for which little toxicity information exists (e.g., tentatively identified compounds) may result in an under-estimation of Site risks.
- Evaluating potential current and future risks (e.g., private well users and future residents) without consideration of the likelihood with which these scenarios may occur over-estimates actual risks.
- Toxicity values may over-estimate risk. Reference doses incorporate conservative uncertainty factors and cancer slope factors estimate upper bound 95th percentile values.
- Risks/doses within an exposure route assumed to be additive. This may result in an over- or under-estimation of risk because using this approach does not take into account antagonistic or synergistic effects.
- Critical toxicity values derived primarily from animal studies may over- or under-estimate risk. There is a fundamental uncertainty in extrapolating animal toxicity data to humans. Several factors may introduce the uncertainty including differences in species, absorption characteristics, pharmacokinetics, target organs, etc.

- Behavioral patterns cannot be predicted with certainty. The Exposure Assessment Section identifies numerous assumptions that are applied to characterizing populations and their potential for exposure to Site contaminants.
- Models used to predict environmental fate and transport of contaminants may over- or under-estimate risk. The air pathway models used have inherent uncertainty in their theoretical ability to accurately predict air concentrations of contaminants.
- Identification of tentatively identified compounds. The associated value is an estimated quantity in which there is presumptive evidence of the presence of the material (tentative identification).
- Other major assumptions used in the risk assessment that would tend to over-estimate Site risks include:
 - There are no groundwater use restrictions.
 - There is the potential for future development of the Site.
- Contaminant concentrations in various media are assumed to remain constant over time (As was noted previously for this assumption, this may result in an over- or under-estimation of exposure because using steady-state conditions does not account for substantial future releases of unmitigated source materials (e.g., to groundwater) that may occur over time, nor does it account for source depletion and attenuation of materials through environmental fate and transport processes).

Diisopropyl ether (DOT)	ug/l	8.100	8.100	8.10		1

This table includes all compounds identified above detection limits in the Upper Aquifer Source Area (see table 7-1 for samples included in this area), and is provided as the starting point in the development of a Set of Chemical Data for use in the Risk Assessment, as discussed in Section 7.1.2.1. Refer to appropriate appendices to determine the total parameters analyzed and their associated detection limits. Refer to appendix U for values used in risk calculations. The data values presented contain a maximum of three significant digits for the results of metals analyses and two significant digits for organic chemical analyses; additional digits are due to limitations in the computer program used to prepare these tables, and do not infer an increase in accuracy. The number of tentatively identified compounds designated as unknowns may exceed the total number of samples analyzed because more than one unknown compound may be present in a given sample.

This table includes all compounds identified above detection limits in the On-Site Containment Area (see table 7-1 for samples included in this area), and is provided as the starting point in the development of a Set of Chemical Data for use in the Risk Assessment, as discussed in Section 7.1.2.1. Refer to appropriate appendices to determine the total parameters analyzed and their associated detection limits. Refer to appendix U for values used in risk calculations. The data values presented contain a maximum of three significant digits for the results of metals analyses and two significant digits for organic chemical analyses; additional digits are due to limitations in the computer program used to prepare these tables, and do not infer an increase in accuracy. The number of tentatively identified compounds designated as unknowns may exceed the total number of samples analyzed because more than one unknown compound may be present in a given sample.

This table includes all compounds identified above detection limits in the Stillbottoms/Treatment Lagoon Area (see table 7-1 for samples included in this area), and is provided as the starting point in the development of a Set of Chemical Data for use in the Risk Assessment, as discussed in Section 7.1.2.1. Refer to appropriate appendices to determine the total parameters analyzed and their associated detection limits. Refer to appendix U for values used in risk calculations. The data values presented contain a maximum of three significant digits for the results of metals analyses and two significant digits for organic chemical analyses; additional digits are due to limitations in the computer program used to prepare these tables, and do not infer an increase in accuracy. The number of tentatively identified compounds designated as unknowns may exceed the total number of samples analyzed because more than one unknown compound may be present in a given sample.

Benzene, 1,1'-oxybis-	ug/kg	7300.000	7300.000	7300.00		1

This table includes all compounds identified above detection limits in the Off-Site Containment Area (see table 7-1 for samples included in this area), and is provided as the starting point in the development of a Set of Chemical Data for use in the Risk Assessment, as discussed in Section 7.1.2.1. Refer to appropriate appendices to determine the total parameters analyzed and their associated detection limits. Refer to appendix U for values used in risk calculations. The data values presented contain a maximum of three significant digits for the results of metals analyses and two significant digits for organic chemical analyses: additional digits are due to limitations in the computer program used to prepare these tables, and do not infer an increase in accuracy. The number of tentatively identified compounds designated as unknowns may exceed the total number of samples analyzed because more than one unknown compound may be present in a given sample.

This table includes all compounds identified above detection limits in the Kapica-Pazmey Area (see table 7-1 for samples included in this area), and is provided as the starting point in the development of a Set of Chemical Data for use in the Risk Assessment, as discussed in Section 7.1.2.1. Refer to appropriate appendices to determine the total parameters analyzed and their associated detection limits. Refer to appendix U for values used in risk calculations. The data values presented contain a maximum of three significant digits for the results of metals analyses and two significant digits for organic chemical analyses; additional digits are due to limitations in the computer program used to prepare these tables, and do not infer an increase in accuracy. The number of tentatively identified compounds designated as unknowns may exceed the total number of samples analyzed because more than one unknown compound may be present in a given sample.

Page 3

MATRIX: Sediment
SOURCE AREA: Drainage Area

CHEMICAL	UNITS	CHEMICAL CONCENTRATION			NUMBER SAMPLES ANALYZED	
		MINIMUM	MAXIMUM	ARITHMETIC MEAN	TOTAL	DETECTED
Tent. Ident. Compound-VOC					18	
Furan, tetrahydro-	ug/kg	160.000	160.000	160.00		1
3-Pentanone, 2,4-dimethyl-	ug/kg	15.000	15.000	15.00		1
3-Heptanone, 5-methyl-	ug/kg	25.000	25.000	25.00		1

This table includes all compounds identified above detection limits in the sediment samples (see table 7-1 for samples included in this area), and is provided as the starting point in the development of a Set of Chemical Data for use in the Risk Assessment, as discussed in Section 7.1.2.1. Refer to appropriate appendices to determine the total parameters analyzed and their associated detection limits. Refer to appendix U for values used in risk calculations. The data values presented contain a maximum of three significant digits for the results of metals analyses and two significant digits for organic chemical analyses; additional digits are due to limitations in the computer program used to prepare these tables, and do not infer an increase in accuracy. The number of tentatively identified compounds designated as unknowns may exceed the total number of samples analyzed because more than one unknown compound may be present in a given sample.

	SV	Butanedioic acid, monomethyl..
	SV	Butanoic acid, 2-methyl-
	SV	Butylcitrate + Unknown
	SV	Diphosphoric acid tetraethy..
	SV	Dodecanoic acid
	SV	Glycine, n-(2-methyl-1-oxo-2...
	SV	Heptanoic acid
	SV	Hexadecanoic acid
	SV	Hexanedioic acid, bis(2-methylpropyl) es
	SV	Hexanedioic acid, dibutylester
	SV	Hexanedioic acid, ethylmethylester-
	SV	Hexanoic acid (DOT)
	SV	Hexanoic acid (DOT)
	SV	Hexanoic acid, 2-ethyl-
	SV	Hexanoic acid, 2-methyl-
	SV	Hexanoic acid, anhydride
	SV	Octanoic acid
	SV	Pentadecanoic acid, 14-methyl-methyleste
	SV	Pentanoic acid, 4-methyl-
	SV	Phenobarbital (VAN)
	SV	Phosphoric acid, triethyles...
	VOA	Propanoic acid, 2-methyl-,butylester-
	SV	Tetradecanoic acid
ACIDS - Unclassified	SV	Unknown alkyl acid
	SV	Unknown carboxylic acid
	SV	Unknown carboxylic acid
	SV	Unknown octadecenoic acid
	SV	Unknown substituted benzoic...
AMINES	SV	Acetamide, n-ethyl-n-phenyl-
	SV	Benamide, n,n-diethyl-3-met...
	SV	Benzenamine, n,n-diethyl-
	SV	Benzenamine, n-ethyl-
	SV	Benzenamine, n-methyl-
	SV	Benzeneacetonitrile
	SV	Benzenesulfonamide, n-butyl-
	SV	Caprolactam
	SV	Cyclopropanamine, 2-phenyl-,...
	SV	Diethylbenzenamine
	SV	Dodecanamide, n,n-bis(2-hydr)-
	SV	Hydroxylamine, o-decyl-
	SV	Silanediamine, 1,1-dimethyl-
	SV	Urea, n-methyl-n'-(4-methylphenyl)-
PCBs	SV	Aroclor 1016
	SV	1,1'-Biphenyl, tetrachloro-
	SV	Trichlorobiphenyl isomer
	SV	PCB
	SV	Unknown chlorinated biphenyl
FURANS	VOA	Tetrahydrofuran
	SV	Furan, 2,2'-[oxybis(methylene)]bis,-
	VOA	Furan, tetrahydro-
	SV	Benzo[B]naphtho[2,3-D]furan
	SV	Furan, 2,2'-methylenebis-
UNCLASSIFIED	SV	Unknown chlorinated compound
	SV	Unknown fatty acid
	VOA	Substituted methylborane
	SV	Unknown substituted sulfonyl
	SV	Unknown + TCL

TABLE 7-11
SUMMARY OF TENTATIVELY IDENTIFIED COMPOUND (TIC) GROUPINGS
AMERICAN CHEMICAL SERVICES NPL SITE
GRIFFITH, INDIANA

TIC GROUP	ANALYSIS TYPE	COMPOUND
	VOA	Unknown
	SV	Unknown
	SV	Iron, tricarbonyl[n-(phenyl-...
	SV	Dihydromethylindene
	SV	Isoquinoline
	VOA	Unknown substituted cyclonex
	SV	Sulfur, mol. (S8)

This table summarizes tentatively identified compounds (TICs) identified in the organic chemical analysis of Site media. TICs were identified from either volatile organic analyses (VOA) or semivolatile organic analyses (SV). TIC groups were selected based on structural similarity of individual compounds.

JDD/KJD

TABLE 7-12

Representative Compounds for
Tentatively Identified Compound (TIC) Groups
American Chemical Service RI/FS
Griffith, Indiana

<u>TIC GROUP</u>	<u>REPRESENTATIVE COMPOUND</u>	<u>HEAST PAGE #</u>	<u>COMMENTS</u>
<u>SUBSTITUTED BENZENES</u>			
#1 Propyl benzenes	Cumene(3)	A-25	Cumene (isopropylbenzene) is similar in structure to compounds in this group.
#2 Propenyl benzenes	Methyl styrene(3)	A-61	Methyl styrene (1-ethenyl-2-methylbenzene) is similar in structure to these compounds, the reference dose is based on an industrial mixture.
#3 Ethylmethyl benzenes	Ethyl toluene(4)(2)	A-82	Insufficient data in HEAST or IRIS. Toxicity addressed by Toluene, a represented TCL.
#4 Diethyl benzenes	Ethyl benzene(2)	A-41	Ethyl benzene, a represented TCL, is similar to these TICs.
#5 Methylpropyl benzenes	Cumene(3)	A-25	Cumene (isopropyl benzene) is similar in structure to these compounds.
#6 Methylethenyl benzenes	Methyl styrene(1)	A-61	Methyl styrene (1-ethenyl-2-methylbenzene) has a RDF and is represented in this group.
#7 Methylphenyl benzenes	Naphthalene(2)	A-63	Naphthalene is similar in structure to this group and is a represented TCL.
#8 Trimethyl benzenes	Trimethylbenzene(4)(2)	A-88	Insufficient data in HEAST or IRIS for trimethyl benzenes. Toxicity addressed by Toluene, a represented TCL.
#9 Dimethylethyl benzenes	Ethyl benzene(2)	A-41	Ethyl benzene or toluene, both represented TCLs, are similar in structure to this group.
#10 Tetramethyl benzenes	Trimethylbenzene(4)(2)	A-88	See #8 above.
#11 Oxygenated benzenes	Benzaldehyde(3)	A-10	Benzaldehyde is similar in structure to this group of compound.

TABLE 7-12
(Continued)

<u>TIC GROUP</u>	<u>REPRESENTATIVE COMPOUND</u>	<u>HEAST PAGE #</u>	<u>COMMENTS</u>
#12 Halogenated benzenes	o-Chlorotoluene(3)(4)	A-22	o-Chlorotoluene (2-chloro-1-methylbenzene) is similar in structure to these compounds, m- and p-chlorotoluene are represented but have inadequate data (HEAST).
#13 Nitro benzenes	Nitrobenzene(3)	A-64	Nitrobenzene is similar in structure to this group.
<u>"SIMPLE" HYDROCARBONS</u>			
#1 Cyclic alkanes	Methylcyclohexane(4)	A-58	Methylcyclohexane is similar in structure to this group. Insufficient data in HEAST or IRIS.
#2 Cyclic alkenes	Vinyl cyclohexane(4)	A-89	4-Vinyl-1-cyclohexene is similar in structure to this group. Insufficient data in HEAST or IRIS.
#3 Halogenated alkanes	1,1,1-Trichloroethane(1)		This TIC group is similar to the numerous halogenated alkanes represented at the site under the TCL.
#4 Straight chain alkanes	n-Hexane(1)(4)	A-48	n-Hexane is similar in structure to this group. n-Heptane (page A-46), and n-Pentane (page A-68) are also similar in structure, however, there is insufficient data in Heast or IRIS.
#5 Branched alkanes	See comments		Branched alkanes not in HEAST or IRIS. This group represented by n-hexane, see #4 above.
#6 Branched alkenes and alkynes	See comments		Branched alkenes not in HEAST or IRIS. This group represented by vinyl cyclohexene, see #2 above.
#7 Ethers	Ethyl ether(1)	A-43	Ethyl ether is represented in this group.
#8 Straight chain alkenes and alkynes	See comments		Straight chain alkenes not in HEAST or IRIS. This group represented by vinyl cyclohexene, see #2 above.

TABLE 7-12
(Continued)

<u>TIC GROUP</u>	<u>REPRESENTATIVE COMPOUND</u>	<u>HEAST PAGE #</u>	<u>COMMENTS</u>
<u>POLYNUCLEAR AROMATICS</u>			
#1 Methylated naphthalenes	Naphthalene(1)		This group is similar to the TCL PAHs which are represented at the site.
<u>PHTHALATES</u>			
#1 Phthalic anhydride	Phthalic anhydride(1)	A69	Phthalic anhydride has a RFD in HEAST and IRIS.
<u>PHENOLS</u>			
#1 Methylated phenols	Cresol(1)		This group is similar to the TCL methylated phenols, which are represented at the site.
<u>KETONES</u>			
#1 Methylated ketones	Acetone(2)	A-1	Acetone and 4-methyl-2-pentanone are TCLs represented at the site and are similar in structure to this group.
#2 Simple ketones	2-Butanone(2)	A-59	2-Butanone (methyl ethyl ketone) is a TCL represented at the site and is similar in structure to this group.
#3 Cyclic ketones	Isophorone(2)	A-49	Isophorone is a TCL represented at the site and is similar in structure to this group.
<u>ALCOHOLS</u>			
#1 Diols	Ethylene glycol(3)	A-42	Ethylene glycol is similar in structure to this group.
#2 Simple alcohols	1-Butanol(3)	A-14	1-Butanol is similar in structure to this group and is represented at the site.
#3 Cyclic alcohols	Benzyl alcohol(2)	A-10	Benzyl alcohol is a TCL represented at the site and is similar in structure to the cyclic alcohols.
#4 Oxygenated alcohols	Ethyl glycol monobutyl ether(1)	A-42	Ethylene glycol monobutyl ether is represented at the site and is similar in structure to the oxygenated alcohols (ethers).

TABLE 7-12
(Continued)

<u>TIC GROUP</u>	<u>REPRESENTATIVE COMPOUND</u>	<u>HEAST PAGE #</u>	<u>COMMENTS</u>
<u>ACIDS</u>			
#1 Cyclic acids	Benzoic acid(2)	A-10	Benzoic acid is a TCL represented at the site, which is similar in structure to this group of compounds.
#2 Non-cyclic acids	Acrylic acid(3)	A-3	Acrylic acid is a non-cyclic acid similar in structure to this group.
<u>AMINES</u>			
#1 Amines	Caprolactam(1)(4)	A-15	Caprolactam is represented at the site and will be used to assess risk from this group. N-Ethylaniline (n-ethylbenzeneamine), page A-33, and n,n-diethyl aniline (n,n-diethylbenzeneamine), page A-41) are also represented at the site, however, inadequate data is available for both (HEAST).
<u>PCBs</u>			
#1 PCBs	TCL Aroclors(2)		This group is similar to the TCL Aroclors, which are represented at the site.
<u>FURANS</u>			
#1 Furans	Tetrahydrofuran(1)	ECAO	The Environmental Criteria and Assessment Office (ECAO) has provided a Rfd for Tetrahydrofuran, this compound will be used to assess toxicity of this group.

Notes:

HEAST = Health Effects Assessment Summary Tables

IRIS = Integrated Risk Information System

(1) TIC has toxicity value.

(2) Group represented by TCL compound on-Site that has toxicity value.

(3) Value obtained from HEAST or IRIS having similar chemical structure.

(4) TIC group - insufficient toxicity data for risk assessment.

e = value unavailable, estimated using DDT
f = value unavailable, estimated using dieldrin
g = value unavailable, estimated using diphenylamine
h = value unavailable, estimated using diphenyl ether

Definitions of chemical properties:

Water Solubility is the maximum concentration of a chemical that dissolves in pure water at a specific temperature and pH. Values are given for a neutral pH and a temperature range of 20 degrees C. The rate at which a chemical is leached from a waste by infiltrating precipitation is a function of its solubility in water. The more soluble compounds are expected to be leached much more readily and rapidly than less soluble chemicals. The water solubilities presented in the literature indicate that, in general, the volatile organic chemicals are more water soluble than the many semivolatile organic compounds (e.g., PAHs, PCBs).

Vapor pressure (VP) provides an indication of the rate at which a chemical in its pure state volatilizes. Values are given for a temperature range of 20 to 30 degrees C. VP is of primary significance where environmental interfaces such as surface soil/air and surface water/air occur. Volatilization is not as important when evaluating groundwater and subsurface soils. Chemicals with higher vapor pressures are expected to enter the atmosphere more readily than chemicals with lower vapor pressures. Vapor pressures for monocyclic aromatic (toluene) and chlorinated aliphatics (TCE) are generally many times higher than vapor pressure for phthalate esters (bis(2-ethylhexyl)phthalate), polynuclear aromatic hydrocarbons (PAHs), and pesticides.

Organic Carbon Partition Coefficient (Koc) is a measure of the tendency for organics to be adsorbed by soil and sediment and is expressed as:

$$Koc = \frac{\text{mg chemical adsorbed/kg organic carbon}}{\text{mg chemical dissolved/liter of solution}}$$

The Koc is chemical specific and is largely independent of soil properties. In general, the Koc is inversely related to its environmental mobility. Values were obtained from the following sources:

U.S. EPA Superfund Public Health Evaluation Manual (SPHEM), 1986

Verschueren, K. Handbook of Environmental Data on Organic Chemicals. Van Nostrand Reinhold Co., New York, 1983.

Weast, R.C. (ed) Handbook of Chemistry and Physics 54th Edition. CRC Press, Cleveland, 1973.

TABLE 7-15

Exposure Pathway Analysis
American Chemical Services RI/FS
Griffith, Indiana

<u>Potentially Exposed Population</u>	<u>Exposure Route, Medium and Exposure Point</u>	<u>Pathway Selected for Evaluation?</u>	<u>Reason for Selection or Exclusion</u>
----- CURRENT LAND USE CONDITIONS -----			
Off-Site residents adjacent to Site.	Ingestion of groundwater from the upper aquifer.	No	Surveys performed at homes adjacent to the Site indicate those with wells in the shallow aquifer do not use them for drinking water; the municipal system is used.
Off-Site residents adjacent to Site.	Dermal contact and incidental ingestion of groundwater from the upper aquifer.	Yes	Some homes adjacent to the Site maintain wells in the upper aquifer and use the water for lawn care and gardening. If contaminated groundwater were to migrate to the off-Site wells, exposure may be possible for garden produce and subsequent human consumption. In addition, children may play in the water (e.g., in swimming pools) and become exposed dermally or through incidental ingestion. However, no testing was performed for these wells because they are not used for drinking water and because if contamination were found, it would be difficult to determine the source, in a region where there exists many industries. Also, the flow of groundwater in the upper aquifer is diverted towards the excavation near the active landfill and by the wetlands which surround the Site, both serving to control off-Site migration of contaminants. Nonetheless, if contaminants in the shallow aquifer migrate to off-Site locations, residents adjacent to the Site may occasionally be exposed, therefore, this pathway was included in the risk assessment.

TABLE 7-15 (Continued)

<u>Potentially Exposed Population</u>	<u>Exposure Route, Medium and Exposure Point</u>	<u>Pathway Selected for Evaluation?</u>	<u>Reason for Selection or Exclusion</u>
Off-Site residents adjacent to Site.	Ingestion and/or other potential exposures to groundwater from the lower aquifer.	Yes	Eight private wells located in the deep aquifer were analyzed during the RI and had no detectable levels of contamination. The ACS and landfill facilities both maintain wells in the lower aquifer; the landfill facility uses their well for drinking water, the use of the well at ACS is for industrial purposes as well as drinking water. There is retardation of contaminant migration vertically due to the confining layer. The potential for exposure to the groundwater in the lower aquifer is considered to be low. Nonetheless, contaminants detected in the lower aquifer were assumed to migrate to off-Site locations where exposure may occur.
Off-Site residents adjacent to Site.	Inhalation of volatiles emissions released from subsurface contaminants.	Yes	The amount of VOCs emanating from the contaminated soils is expected to be low compared to that from the ACS facility and from the air in this region of heavy industry. No samples were taken in the field because of the difficulty in distinguishing air pollutant sources and anthropogenic background. It should be recognized that volatiles released from the Site may pose an exposure to off-Site residents. Predicting the amount of exposure quantitatively would be difficult given the current conditions. Nonetheless, an emission and dispersion model was used to estimate potential releases to air from subsurface contamination.
Off-Site residents adjacent to Site.	Inhalation of fugitive dusts emanating from surface contamination at Kapica/Pazmey.	Yes	There exist unvegetated areas of surface soil contamination at Kapica/Pazmey. These soils may be disturbed via wind erosion and disperse contaminated particulates to off-Site locations. The greatest impact is likely to be on-Site. A particulate erosion and dispersion model has been used to estimate exposure from this pathway.
Off-Site residents adjacent to Site.	Ingestion of garden vegetables and fruits.	No	This pathway was not considered to present substantial risk.
Off-Site residents adjacent to Site.	Fishing, hunting and trapping; terrestrial and aquatic species for consumption.	No	The wetlands do not support fish populations. Hunting and trapping are considered low potential exposure pathways because of small user groups.
Adolescents playing (trespassing) on-Site.	Inhalation of volatiles released from the Site.	Yes	Similar to off-Site residents, estimating exposure via this pathway under current conditions utilized an emissions and dispersion model.

TABLE 7-15 (Continued)

<u>Potentially Exposed Population</u>	<u>Exposure Route, Medium and Exposure Point</u>	<u>Pathway Selected for Evaluation?</u>	<u>Reason for Selection or Exclusion</u>
Adolescents playing (trespassing) on-Site.	Inhalation of fugitive dusts at Kapica/Pazmey.	Yes	Wind erosion may contribute to the total exposure for a trespasser coming on-Site at Kapica/Pazmey.
Adolescents playing (trespassing) on-Site.	Incidental ingestion of, and dermal contact with, contaminated soils on-Site.	Yes	Surface contamination is evident at Kapica/Pazmey. Children playing (trespassing) on-Site at this location may be exposed occasionally via the pathways indicated. Other areas of the RI/FS Site where contaminated soils exist are covered with clean material and/or have extreme access limitations (i.e., ACS).
Adolescents playing (trespassing) on-Site.	Incidental ingestion of, and dermal contact with, contaminants detected in wetland surface water and sediments and in drainage ditches.	Yes	This pathway is evaluated to assess the risks associated with surface water and sediment. Contamination has been detected in these media.
On-Site workers at the ACS facility.	Direct contact with soils, sediments and lagoon waters.	No	Contaminated soils and sediments have been covered by clean cover material and/or, building construction. The surface water in the lagoon has been analyzed and indicates low contamination. The lagoon is the only surface water feature on the Site. In addition, workers on-Site wear health and safety protection, and must comply with OSHA safety requirements.
On-Site workers at the ACS facility.	Inhalation of airborne contaminants emanating from the Site.	Fugitive Dusts - Yes Volatiles - Yes	Contaminated soils are covered by clean cover material effectively minimizing the potential for generation of contaminated fugitive dust. Volatiles released from subsurface soils to the ambient air may occur, however, exposure to volatiles released from operating processes is likely more substantial. Analysis of volatiles released from subsurface soils has not been performed because of the difficulty in obtaining meaningful estimates of exposure point concentrations given the contributions of pollutants to the air from the ACS facility and anthropogenic background. Nonetheless, emissions and dispersion models have been used to estimate release of volatile contaminants from subsurface materials to the air.
On-Site workers at the ACS facility.	Ingestion and/or other potential exposures to groundwater from the lower aquifer.	No	ACS maintains 4 wells in the deep aquifer, more than 300 ft below the ground surface, in bedrock.

TABLE 7-15
(continued)

<u>Potentially Exposed Population</u>	<u>Exposure Route, Medium and Exposure Point</u>	<u>Pathway Selected for Evaluation?</u>	<u>Reason for Selection or Exclusion</u>
----- POTENTIAL FUTURE LAND USE CONDITIONS -----			
Hypothetical resident living on-Site.	Ingestion of and dermal contact with groundwater from the upper aquifer. Inhalation of volatiles released while showering.	Yes	Hypothetical.
	Ingestion of and dermal contact with groundwater from the lower aquifer. Inhalation of volatiles released while showering.	Yes	Hypothetical.
	Dermal contact with and incidental ingestion of unearthed subsurface soils.	Yes	Hypothetical - to address risks associated with subsurface soils, it was assumed that contaminated subsurface soils are unearthed and present direct exposure potential to residents living on-Site.
	Direct contact with and incidental ingestion of sediments.	Yes	Similar exposure as current use scenario.
	Direct contact (dermal and incidental ingestion) with surface water.	Yes	Similar exposure as current use scenario.
	Inhalation of volatiles released to air on-Site.	Yes	24-hour/day exposure to volatiles.
	Inhalation of particulate released from unearthed subsurface soils.	No	Assume vegetative cover in residential setting minimizes this pathway; addressed under current use scenario.

Exposure Point Concentrations for each chemical are either the 95 % UCLM or the maximum detected concentration, whichever is smaller, for each area and medium, based on the criteria of being positively detected at least once, at a concentration greater than background levels and blank sample levels. all groundwater values are maximum concentrations per U.S.EPA (This table is a summary (c) indicates a carcinogenic PAH.

NOTES:

1) A reference dose (RFD) is derived from a pertinent toxicity study(s), and is an estimate of the "safe" level of chemical intake over a set length of exposure (e.g., chronic) for humans. Many assumptions must be made when predicting this "safe" chemical intake level (i.e., RFD) from a laboratory study. Uncertainty factors (UFs) are applied when estimating the RFD for the following reasons.

- A UF of 10 is used to account for variation in the general population and is intended to protect sensitive subpopulations (e.g., elderly, children).
- A UF of 10 is used when extrapolating from animal data to humans. This factor is intended to account for the interspecies variability between humans and other mammals.
- A UF of 10 is used when a RFD is derived from a subchronic instead of a chronic toxicity study.
- A UF of 10 is used when a lowest adverse effect level (LOAEL) is used instead of a no adverse effect level (NOAEL) to derive a RFD. This factor is intended to account for the uncertainty associated with extrapolating from toxic levels of chemical exposure (i.e., LOAEL) to nontoxic levels of chemical exposure (i.e., NOAEL).

In certain cases, a modifying factor (MF) is used to account for further uncertainty associated with the toxicity study used to develop the RFD. The MF may vary from >0 to 10.

The uncertainty factors presented in this table represent the product of all the uncertainty factors (and modifying factors) used to derive the RFD (e.g., $10 \times 10 \times 10 = 1000$).

Table 7-18
(continued)

Page 14

- 2) This code represents the U.S. EPA weight-of-evidence classification system for carcinogenicity for chemicals. The following is a description of the classification by group.

<u>Group</u>	<u>Description</u>
A	Known human carcinogen
B1 or B2	Probable human carcinogen
	B1 indicates that limited human data on the carcinogenicity of the chemical are available.
	B2 indicates sufficient evidence of carcinogenicity in animals and inadequate or no evidence of carcinogenicity in humans exists.
C	Possible human carcinogen
D	Not classifiable as to human carcinogenicity
E	Evidence of noncarcinogenicity for humans

- 3) The slope factor for benzo(a)pyrene was used to represent the carcinogenic potential of the carcinogenic polynuclear aromatic hydrocarbons (PAHs).
- 4) Toxicity values have been developed separately for ingestion of cadmium in water and cadmium ingestion with solids (i.e., food or soil).
- 5) Tentatively identified compounds (TICs) were grouped based on similar chemical structure. Compounds of similar chemical structure are assumed to have similar toxicological properties. For each TIC grouping, a representative compound was chosen for which there was a reference dose (RFD). The RFD for the representative compound was used to represent the toxic potential of the particular TIC group.
- 6) The information in this table was summarized from U.S. EPA's "Health Effects Assessment Summary Tables" (Fiscal Year - Annual, 1991).

LEGEND

-- = information not available

data inadequate = presently, toxicity data is inadequate for reference dose or slope factor derivation.

This table presents risk values for chemicals of potential concern which are associated with hazard quotients greater than 0.01 or cancer risks greater than 1.0e-06. Chemicals of potential concern with risk values less than both of these levels are not shown.

Hazard quotients and cancer risks are unitless values which represent the probability of incurring an adverse health effect. These risk values are calculated using the following relationships:

$$\text{Hazard Quotient} = \text{Chronic Daily Intake} / \text{Reference Dose}$$

$$\text{Cancer Risk} = \text{Chronic Daily Intake} \times \text{Slope Factor}$$

Hazard quotients and cancer risks are summarized for applicable routes of exposure. Values for each route are summed to arrive at an exposure pathway total risk value. The percentage of total risk is also shown for each compound.

In some cases risks were not determined (ND) because reference doses or slope factors were not available.

This table presents risk values for chemicals of potential concern which are associated with hazard quotients greater than 0.01 or cancer risks greater than 1.0e-06. Chemicals of potential concern with risk values less than both of these levels are not shown.

Hazard quotients and cancer risks are unitless values which represent the probability of incurring an adverse health effect. These risk values are calculated using the following relationships:

Hazard Quotient = Chronic Daily Intake / Reference Dose

Cancer Risk = Chronic Daily Intake x Slope Factor

Hazard quotients and cancer risks are summarized for applicable routes of exposure. Values for each route are summed to arrive at an exposure pathway total risk value. The percentage of total risk is also shown for each compound.

In some cases risks were not determined (ND) because reference doses or slope factors were not available.

Table 7-17
CHEMICAL TOXICITY VALUES AND ABSORPTION ESTIMATES
USED FOR RISK QUANTIFICATION

American Chemical Services MPL Site
Remedial Investigation
Griffith, Indiana

Notes:

Toxicity values were obtained from the U.S. EPA's Integrated Risk Information System (IRIS), U.S. EPA's "Health Effects Assessment Summary Tables" (HEAST, Annual FY-1991), and information provided by U.S. EPA Environmental Criteria Assessment Office (ECAO). Toxicity values for the TIC groupings are values for the representative compounds.

Chemical specific information pertaining to the oral and dermal absorption of compounds was provided by ECAO. In the absence of chemical specific values, it was assumed that the oral absorption efficiency for organic compounds and metals was 50 % and 5 %, respectively. The dermal absorption estimates were assumed to be 30% for organic compounds and 1.0 % for metals. The oral and dermal absorption estimates are presented as unitless values where 1.0 represents 100 % (complete) absorption. Chemical-specific dermal permeability constants were obtained from the U.S. EPA "Superfund Exposure Assessment Manual" (SEAM) 1988, or the ECAO. As required by the U.S. EPA, when chemical-specific information is not available, default values were assigned to represent chemical permeability, as footnoted.

Reference Doses and Slope Factors designated for the dermal route of exposure are not provided in the U.S. EPA information sources, but were calculated from corresponding values for the oral route of exposure. These values are used to calculate risks associated with chemical dose estimates based on an absorbed (in contrast to an administered) level of chemical. All chemical dose estimates for the dermal route of exposure are based on absorbed chemical levels. The following relationships were used to derive dermal toxicity values:

Oral Reference Dose (administered) x Oral Absorption Estimate = Dermal Reference Dose (absorbed)
Oral Slope Factor (administered) / Oral Absorption Estimate = Dermal Slope Factor (absorbed)

FOOTNOTES - (listed to the right of the value)

- I = Verified in IRIS '5/15/91
 - H = Values from HEAST FY-1991
 - D = 'Data inadequate for quantitative risk assessment' (HEAST); applies to all RfDs for this compound.
 - ND = Value not determined for this compound.
 - C = Values from Interim Guidance for Dermal Exposure Assessment. (OHEA-E-367, 3/91, Review Draft)
 - S = Values from the Superfund Environmental Assessment Manual (EPA/540/1-88/001) Table A-4.
 - * = Value updated 5/91 (Revised from draft risk assessment)
 - 1 = Value withdrawn by IRIS pending further review.
 - 2 = Compound under IRIS review.
 - 3 = Total carcinogenic PAHs; RfDs and SF values from Benzo[a]pyrene used.
 - 4 = Nickel slope factor for nickel refinery dust.
 - 5 = IRIS not queried for this compound
 - 6 = Values from ECAO Technical Support Center.
 - 7 = Baranowska-Dutkiewicz, B. 1981. Absorption of Hexavalent Chromium in Man. Arch. Toxicol., 47: 47-50.
 - 8 = Value for endosulfan used for endosulfan sulfate.
- Dermal Permeability Constant Default Values:
- Volatiles - Toluene (1.01e+00) as required by U.S.EPA.
 - Semivolatiles - 2-Butanone (5.0e-03) as required by U.S.EPA.
 - Pesticides - Values from ECAO. Total PCBs use Aroclor 1248.
 - Inorganics - water (1.5e-03)

Total hazard risk less than 0.01				
Total Cancer risk less than 1e-6				
	Total 3.9e-04	Total 100%	Total 2.0e-09	Total 100%

This table presents risk values for chemicals of potential concern which are associated with hazard quotients greater than 0.01 or cancer risks greater than 1.0e-06. Chemicals of potential concern with risk values less than both of these levels are not shown.

Hazard quotients and cancer risks are unitless values which represent the probability of incurring an adverse health effect. These risk values are calculated using the following relationships:

Hazard Quotient = Chronic Daily Intake / Reference Dose

Cancer Risk = Chronic Daily Intake x Slope Factor

Hazard quotients and cancer risks are summarized for applicable routes of exposure. Values for each route are summed to arrive at an exposure pathway total risk value. The percentage of total risk is also shown for each compound.

In some cases risks were not determined (ND) because reference doses or slope factors were not available.

This table presents risk values for chemicals of potential concern which are associated with hazard quotients greater than 0.01 or cancer risks greater than 1.0e-06. Chemicals of potential concern with risk values less than both of these levels are not shown.

Hazard quotients and cancer risks are unitless values which represent the probability of incurring an adverse health effect. These risk values are calculated using the following relationships:

Hazard Quotient = Chronic Daily Intake / Reference Dose

Cancer Risk = Chronic Daily Intake x Slope Factor

Table 7-28

This table presents risk values for chemicals of potential concern which are associated with hazard quotients greater than 0.01 or cancer risks greater than 1.0e-06. Chemicals of potential concern with risk values less than both of these levels are not shown.

Hazard quotients and cancer risks are unitless values which represent the probability of incurring an adverse health effect. These risk values are calculated using the following relationships:

Hazard Quotient = Chronic Daily Intake / Reference Dose

Cancer Risk = Chronic Daily Intake x Slope Factor

Hazard quotients and cancer risks are summarized for applicable routes of exposure. Values for each route are summed to arrive at an exposure pathway total risk value. The percentage of total risk is also shown for each compound.

In some cases risks were not determined (ND) because reference doses or slope factors were not available.

This table presents risk values for chemicals of potential concern which are associated with hazard quotients greater than 0.01 or cancer risks greater than 1.0e-06. Chemicals of potential concern with risk values less than both of these levels are not shown.

Hazard quotients and cancer risks are unitless values which represent the probability of incurring an adverse health effect. These risk values are calculated using the following relationships:

Hazard Quotient = Chronic Daily Intake / Reference Dose

Cancer Risk = Chronic Daily Intake x Slope Factor

Hazard quotients and cancer risks are summarized for applicable routes of exposure. Values for each route are summed to arrive at an exposure pathway total risk value. The percentage of total risk is also shown for each compound.

In some cases risks were not determined (ND) because reference doses or slope factors were not available.

This table presents risk values for chemicals of potential concern which are associated with hazard quotients greater than 0.01 or cancer risks greater than 1.0e-06. Chemicals of potential concern with risk values less than both of these levels are not shown.

Hazard quotients and cancer risks are unitless values which represent the probability of incurring an adverse health effect. These risk values are calculated using the following relationships:

Hazard Quotient = Chronic Daily Intake / Reference Dose

Cancer Risk = Chronic Daily Intake x Slope Factor

Hazard quotients and cancer risks are summarized for applicable routes of exposure. Values for each route are summed to arrive at an exposure pathway total risk value. The percentage of total risk is also shown for each compound.

In some cases risks were not determined (ND) because reference doses or slope factors were not available.

Table 7-38

Table 7-38
(Continued)

- (*) Total population hazard indices and cancer risks for future Site residents were calculated by incorporating values for groundwater in the upper aquifer.
- (1) In addition to the current use exposures that exist for each population as described above, it is possible that a trespasser may also be an off-Site resident, and on-Site workers may be an off-Site resident. Thus, while pathways have been combined for each individual population, populations have also been combined, as appropriate (e.g., off-Site resident and trespasser) to evaluate the maximum exposure of a population through current land use conditions that is reasonably expected to occur at the Site.
 - (2) The amount of exposure time to contaminants in air as a trespasser (3 hours/day, 52 days/year, 10 years) is 1.2% of the off-Site resident (24 hours/day, 182 days/year, 30 years). Because making this adjustment does not significantly alter the total multi-population risk, individual population risks were directly added in order to evaluate maximally exposed population risks.
 - (3) Similarly, ACS exposure to contaminants in air while working on-Site (8 hours/day, 130 days/year, 30 years) is 23.8% of the exposure conditions assumed for the off-Site resident (24 hours/day, 182 days/year, 30 years). This difference does not have a substantial impact on the total multi-population risk. Individual population risks were directly added in order to evaluate maximally exposed population risks.

FIGURES

FOOTNOTES

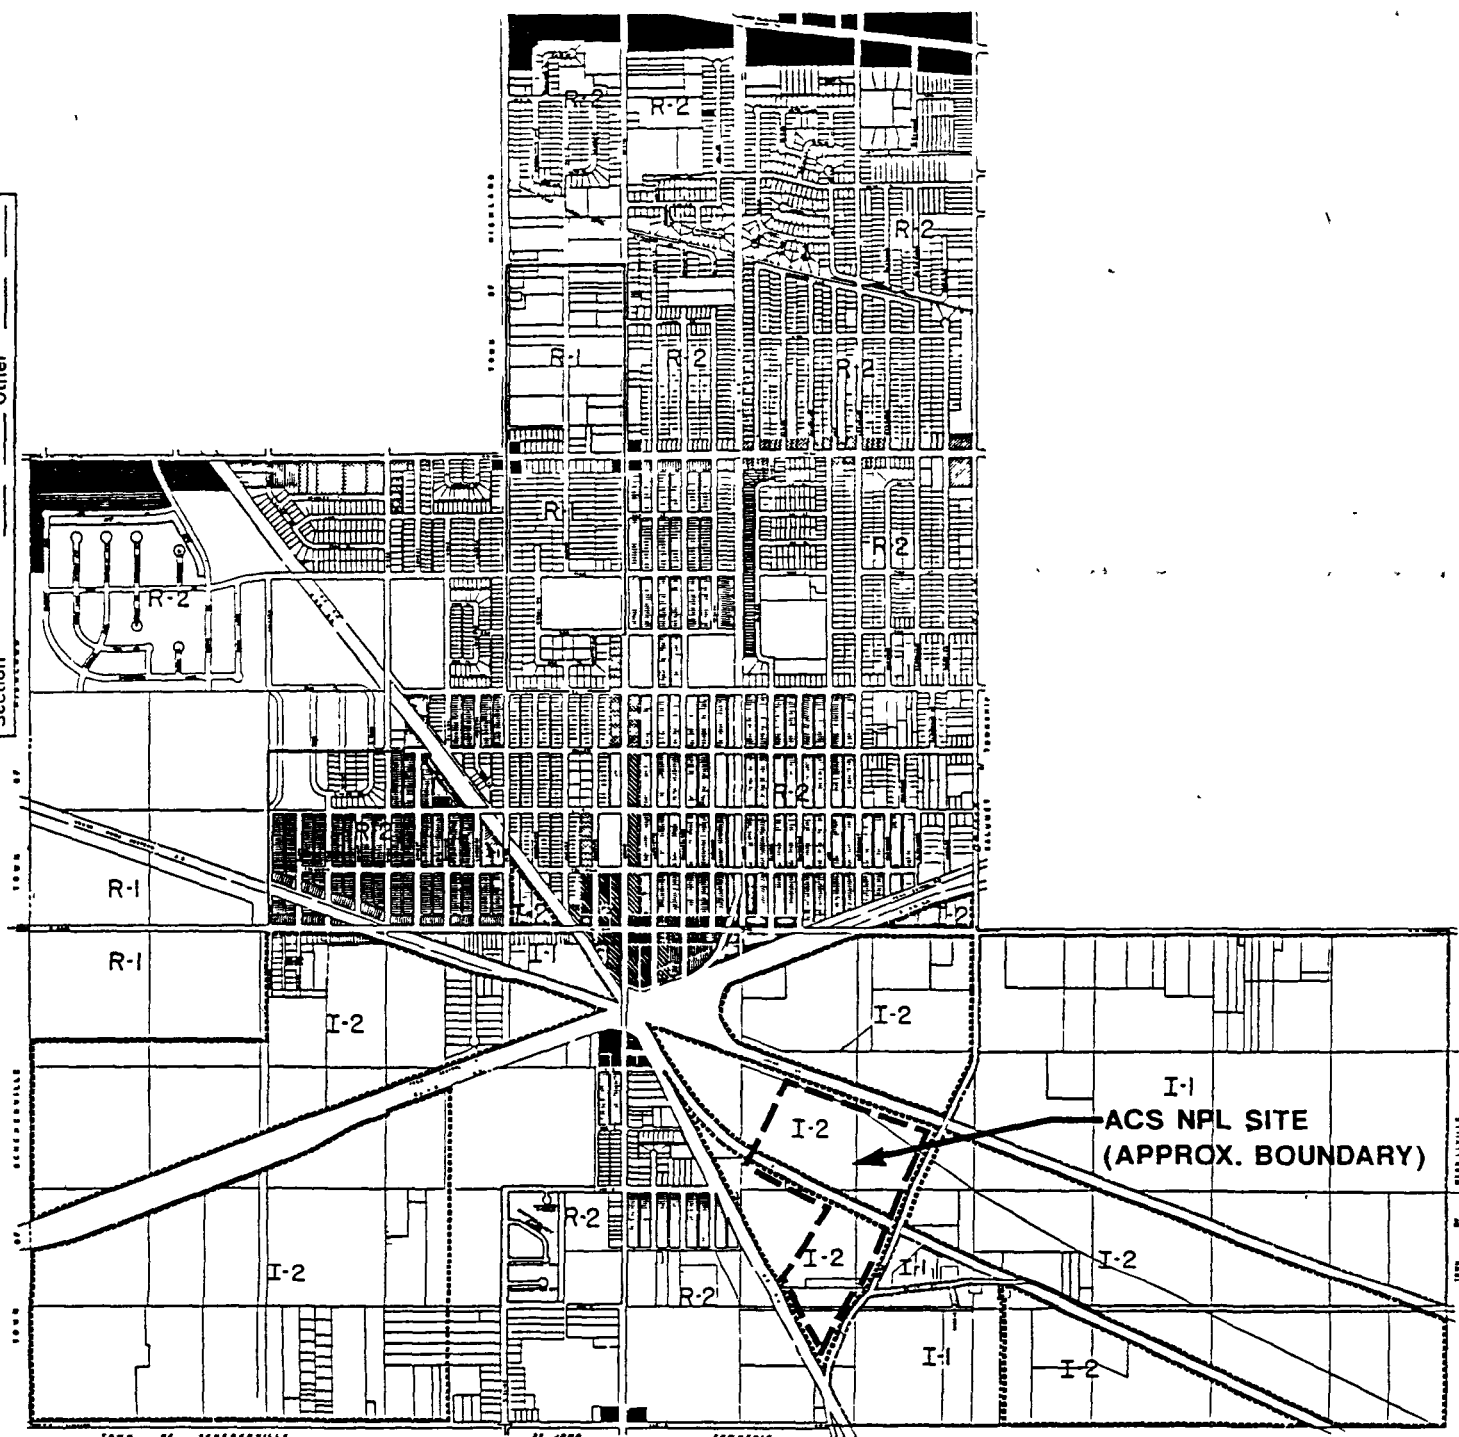

- (1) TIC has toxicity value.
- (2) Group represented by TCL compound on-site, that has toxicity value.
- (3) Value obtained from HEAST or IRIS having similar chemical structure.
- (4) If insufficient toxicological data is available according to HEAST or IRIS; no toxicity value is assigned to the group.

HEAST = Health Effects Assessment Summary Tables
 IRIS = Integrated Risk Information Systems
 TIC = Tentatively Identified Compound
 TCL = Target Compound List
